come an important crop in the United States and in
nada, though rather for industrial than dietetic pur-
ses. In Europe it has been increasingly used for food,
pecially in war-time, and has acquired a position of
eem.

The composition of the soya bean is unique. Its protein
ntent (N × 6·25) is estimated as running from 33% to
%, whereas the pulses generally have but 20–23%:
leed no foods except cooked lean meat, or a hard cheese
ade from skimmed milk, come anywhere near it in
otein content. Another advantage is its high percentage
oil, with much unsaturated fatty acid in its triglycer-
es. No ordinary pulse contains much fat, though the
anut resembles the soya bean in this characteristic.
nally its carbohydrates are not starch but dextrins,
d there is more calcium and iron than in other pulses.
om all this the value of soya bean as a food seems
yond doubt, if the disadvantage of its bitter taste can
eliminated—as it can. At the least its high protein
ntent recommends its consumption when other protein
scarce; for even if the quality of the protein is low,
quantity may make up for this. Actually the earlier
alyses of the amino-acid content of glycinin (the chief
otein of soya bean) suggested that its quality is not
v. Osborne and Clapp[8] demonstrated the presence
leucine, tyrosine, arginine, lysine, and histidine in
r amount; Jones and Waterman[9] added tryptophan;
onka and Jones[10] raised the last workers' estimate
30%; and Barnes and Maack[11] showed that methi-
ine was present to 1·8%. Hence, though cystine and
ethionine are not well represented, soya protein has
l the essential amino-acids investigated up to date.

So much for the armchair arguments for the use of
ya bean as food—arguments which have led Henry
rd to cultivate it at Dagenham, and Hitler (they say)
give it to his storm troops. Unfortunately when we
rn to accurate experiment on animals and human
ings the case falls to the ground. Aykroyd and
ishnan,[12] well before the late war, showed that addition
soya bean to the diet of mission school-children
proved their growth-rate not a whit, whereas skim-
lk powder improved it remarkably. And now the
ole subject has been reinvestigated by a subcommittee
the Nutrition Advisory Committee of the Indian
search Fund Association.[13] Working with young and
ult rats and human beings, experiments were made
the biological values of soya bean and other pulses,
d the effect of soya bean and other supplements on the growth of rats and of children was tested in the Universities of Dacca and Lahore, the Seth G.S. Medical College, Bombay, and the Nutrition Research Laboratories, Coonoor. The results were concordant and led to the conclusion that "although soya bean contains more of fat, minerals, vitamins and 'available' proteins than other pulses, it has, for some unknown reason, not proved itself superior to other pulses within the range of experiments reported. . . . Taking the results obtained so far into consideration, the subcommittee is of the opinion that as a supplement to typical Indian diets based on cereals, but adequate in quantity, soya bean has no special advantages over common Indian pulses."

Of course, as the committee says, this is not the last word on the nutritive value of the soya bean; but it seems to be losing a little of its prestige.

A DIFFICULT DIAGNOSIS

IT has been said that serious disease is nowhere more liable to be overlooked than when it affects the pericardium.[1] Certainly tuberculous pericarditis, with its insidious onset and its confusing early symptoms, may easily escape diagnosis, and is probably more common than is generally believed.[2,3] The onset, unlike that of rheumatic pericarditis, is seldom associated with pain; the accumulation of fluid, being gradual, is well supported, and a very large effusion may form before attention is attracted by signs of mediastinal pressure; indeed as much as 2–3 litres has been aspirated. The fluid is more often blood-stained than serous, and it may be difficult to demonstrate tubercle bacilli either by culture or by guineapig inoculation. A further cause of difficulty is that the constitutional disturbances of active tuberculosis which attend the pericarditis itself may easily be attributed to the primary lesion in the lung, pleura, or spine, and diagnosis is then delayed until the development of cardiac tamponade. Sometimes, however, the condition arises in a patient (of any age) who has been in good health until a recent influenza-like illness; in these cases infection of the pericardium is attributed to direct lymphatic spread from reactivated tuberculous mediastinal or hilar glands; and prompt diagnosis is particularly important since the primary treatment is that of the underlying tuberculous focus.

If the patient survives, he develops the features characteristic of Pick's disease—enlarged liver, ascites, muffled heart-sounds, and small pulse-pressure—for which surgical treatment now offers the chance of dramatic cure. It may be that in future early recognition of tuberculous pericarditis and improved treatment will arrest the disease before this stage of constrictive pericarditis is reached. The induction of a pneumopericardium, already helpful in diagnosis, may also find a place in therapy. The value of local penicillin in acute coccal pericarditis is already established.[4] Is it too much to hope that antibiotics of the streptomycin group will provide the remedy for a condition which has hitherto resisted active medical treatment?

ACCORDING to present plans the House of Lords will consider the National Health Service Bill on Oct. 8 and 9, immediately after their return from the summer recess.

CALCIUM CARBONATE IN NATIONAL FLOUR.—The Minister of Food announces that, on the advice of the special diets advisory committee of the Medical Research Council, from Aug. 11 the rate of addition of calcium carbonate (creta *præparata*) to national flour has been increased from 7 oz. to 14 oz. per sack of 280 lb. This, it is stated, is to compensate for the increased content of phytic acid in 90%-extraction flour.

NUTRITIONAL RETROBULBAR NEURITIS

NUTRITIONAL OPTIC NEUROPATHY

D. FITZGERALD MOORE
M.R.C.S., D.T.M. & H.
LATE SENIOR MEDICAL OFFICER, WEST AFRICAN MEDICAL (COLONIAL) SERVICE

RETROBULBAR neuritis has been one of the most common nutritional diseases affecting prisoners-of-war (P.O.W.) and internees in the Far East. The repatriation of these patients has provided material for further investigation in this country, where formerly it had not been observed. In this paper I compare the information more recently acquired with the results of earlier work, and draw some conclusions about the prevention of this and associated conditions in other parts of the world.

Before doing so, I wish to acknowledge the splendid morale of the prisoners and the extremely fine work done by the medical officers to limit malnutrition by planning the available rations so as to achieve the best qualitative results and by devising ingenious methods of obtaining or developing extra sources of supply. Without doubt many lives were saved, and a firm control was gained over a situation which must otherwise have proved catastrophic.

The conditions, however, were such that a high incidence of malnutrition could not be prevented. Supplies of such essentials as 'Marmite' and dried brewers' yeast—both preventive and curative of this ophthalmic condition in its early phases—could have been available only in very moderate amounts; and, though thiamine and nicotinic acid were apparently more plentiful and put to the fullest possible use, other synthetic vitamins were also limited.

It has been shown (Nutrition Society 1946, Williamson 946) that the P.O.W. were confined in two main areas—in Formosa and the northern area, and in Malaya. In both areas energy food values were fairly well maintained, but there were well-marked differences in the type and quality of the diets. In Formosa and the northern area the main source of carbohydrate was unpolished rice, or if the rice was polished it was often reinforced with barley in the earlier period of captivity. Soya bean was also supplied in fair amount. But in Malaya the rice was polished and of exceptionally poor quality, and it was not reinforced with natural foodstuffs. Also the protein was much more limited. In Formosa nutritional retrobulbar neuritis and keratitis (riboflavine deficiency), though common in the later period of captivity, was far less in evidence than in Malaya.

It has been generally accepted by those in charge that there was no real shortage of vitamins A and C, though there was a shortage of fats. But vitamin A was amply provided by the green leafy food, the extreme value of which was at once recognised, every possible means being taken to extend supplies. It has also been accepted that the outstanding vitamin deficiencies were those of the vitamin-B complex. The most instructive dietary tables, drawn up in the camps, demonstrate these facts in great detail.

Thiamine, though it could cure and prevent beriberi (in one camp, after the first initial outbreaks, beriberi was kept almost entirely in abeyance), could neither prevent nor cure retrobulbar neuritis. In general the results of treatment in nutritional retrobulbar neuritis were disappointing, but conditions were all against a successful issue.

If full use is to be made of this newer evidence, in the interests both of research and of nutrition, it is necessary to compare with these conditions which caused retrobulbar neuritis other known conditions which also have been shown to cause it, and the different circum stances in which it can arise, in the hope that som common factor or factors will emerge and point mo definitely to the cause. For these purposes it is necessar to present again some of the known facts.

SIGNS AND SYMPTOMS

"Dimness of vision" or "indistinctness of vision has been recognised for many years as associated eith with secondary pellagra (Calhoun 1918, Carroll 193 or with the common tropical syndrome now identifie (Sebrell and Butler 1938, Sydenstricker et al. 1939, Kru et al. 1940) as hyporiboflavinosis. Excluding earli Japanese knowledge, the first real recognition of th syndrome was made in 1911 by Stannus, who not onl described the general signs and symptoms but also dre attention to its association with pellagra. This, as a guid to subsequent investigation, seems to be a vital link.

In 1918 Scott described an acute condition whi he believed to be toxic and which he called "t central neuritis of Jamaica." This occurred amon coolies there whose diet consisted almost entirely sugarcane. Among the general signs and sympton were "itching of the eyes, congestion of the conjunctiv slight photophobia, indistinctness of vision, burnin sensations of the mouth, numbness and burning of th feet, and in some cases ataxia." Meagher (1936) ident fied a similar condition in the Solomon Islands. I Sierra Leone Wright (1928) described a condition whic was identical with that described by Stannus, and whic in 1930, in a privately printed report, he called the A an B avitaminosis of Sierra Leone. He was the first t introduce active treatment. In Nigeria I (Moore 193 reported on defective vision associated with the sam syndrome among school-children. I then viewed th visual condition as either a toxic amblyopia or a retr bulbar neuritis. Later (Moore 1932) the diagnosis retr bulbar neuritis was finally preferred and from that dat has been constantly used. Still later (Moore 193 the term "nutritional" was added on the suggestion McCarrison. There are, however, some points it is fe advisable to restate here. The fundus appearanc may vary greatly, though most commonly they are i keeping with a retrobulbar neuritis (partial optic atrophy But some cases, even of long duration, showed no chang at all, and in others a frank primary atrophy was sim lated, and more exceptionally optic neuritis. Dansey Browning (1946), Rich (1946), and Dansey-Brownin and Rich (1946) in their helpful and detailed clinic reports on released P.O.W. have made similar observa tions. To meet all considerations, a more gener term may be required, and "nutritional optic neur pathy" (as has been suggested) is a reasonable one.

Landor and Pallister (1935) recognised the syndrom in a Malay prison, and included "dimness of vision among the symptoms described. They found co liver oil useless. They were the first to use autoclave marmite in the more general condition.

Jimenez Garcia (1940), in Spain, investigated a simil syndrome among Europeans during the civil war 1936–39. He also described a retrobulbar neuritis. H believes the condition is a B_2-complex deficiency. This ver important work has been insufficiently recognised in th country. There were many cases not only of retrobulba neuritis but also of other effects of vitamin-B deficiency and results of therapeutic trials. A study of the condi tions in the siege of Madrid must bear valuable com parisons with the privations undergone in the Far East.

More recent contributions are those of Wilkinson an King (1944) in China, and of Dansey-Browning (1946) Rich (1946), Dansey-Browning and Rich (1946), Garlan (1946), Ridley (1945), Spillane (1945), Spillane an Scott (1945), and R. E. Wright (1946) in this countr on released P.O.W., besides the reports of the medica ers in charge of the P.O.W. and internee camps, to m special acknowledgment has already been made.

TREATMENT

n Nigeria, from 1931 onwards, treatment in the early ses of this condition was generally successful (see s. 1–3). The following is a typical example from many ers quoted in published work.

Nov. 13, 1937: an Ibo, aged 15 years, a thin depressed y, with skin grey and dry, severe perlèche dry scaly otum, raw red tongue, burning of the feet, and photo-obia. Mother says he was cheerful before onset Vision fective February, 1937, severely so by March In June was forced to leave school, as he could only "listen in ss" Mother a petty trader. Diet: manioc 4 "cups" ll daily, stockfish, red-palm oil, some green leaf, a small nount of meat occasionally, peppers, and salt Vision 1/60. nable to read print. Both disks, optic neuritis. Treat-ent: autoclaved marmite, one "cigarette tin" full weekly.

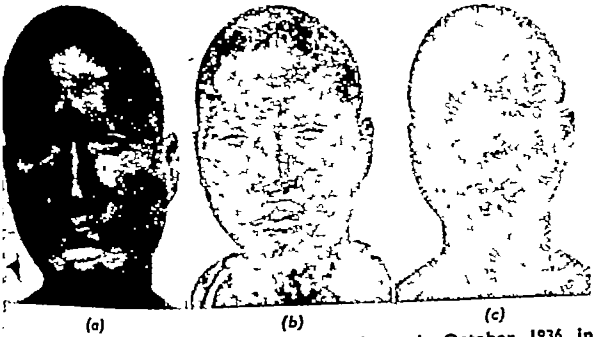
Nov. 26: mouth and perlèche entirely healed, scrotum etter. Vision 5/60 J.20 pt.

Dec. 12: 6/36 J.12 pt.

Dec 31: 6/12 J 8 pt. Skin shiny and bright, whole appear-nce altered, and patient delighted with progress

Feb. 11, 1938: 6/6 J.1 pt.

If, however, treatment was delayed over six months, r perhaps a year, irreversibility became more manifest nd increased with time. It appears to me that this factor has been the essential one which has counted so much among P.O.W. and not, as some would maintain, an irreversibility from the start of the illness.



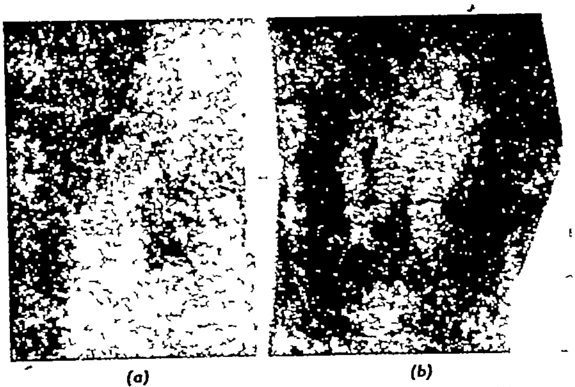
(a) (b) (c)

Fig. 1—"Joe," a Sierra Leonean, seen at Lagos in October, 1936, in conjunction with Dr. G. E. Dodds (now Senior Medical Officer, Nigeria): vision 5/60, 4/60, severe changes in optic nerves, and ataxia; history over two years; staple diet rice and manioc; (a) on first attendance; (b) after five days' treatment with marmite; (c) after eleven days' treatment. Visual condition was not followed up, as he was a member of a ship's crew in port only for that period.

With regard to prognosis, it was possible in Nigeria to follow up many cases for some years. Once the offending cause was removed, they did not worsen. This, it is felt, is of great importance so that patients may be reassured.

ÆTIOLOGY

The ætiology of nutritional retrobulbar neuritis in relationship to the more classical syndromes is still far from complete. I am satisfied, however, that it can be excluded from beriberi, though it can be associated therewith. The response I obtained with autoclaved yeast on the visual condition made this clear (Moore 1939). The investigations with thiamine in the P.O.W. camps surely brings further and impressive evidence against beriberi. In West Africa nearly all cases were either accompanied or preceded by hyporiboflavinosis (see also Hughes 1946). But it would not be safe to state that riboflavine deficiency caused the neural condition, for trials with riboflavine have never been sufficiently extended. Such tests are much more tedious and exacting in interpreting these findings than those directed to the more obvious skin and mouth conditions. Lack of riboflavine is no doubt an important causal factor, but other vitamins of the B complex, excluding thiamine, may also share in the cause, a view that has also been expressed by Stannus. The same is partly true for nicotinic acid, though there is more evidence that lack of this vitamin is not directly concerned. Experiences in P.O.W. camps appear also to support this view.



(a) (b)

Fig. 2—Same case as fig. 1: rashes on flexor aspects of (a) arm, and (b) leg, on first attendance.

Therapeutic investigation, therefore, by exclusion trials has reached a definite but only intermediate stage. Treatment has yielded important results, provided it is begun early, the dosage (marmite or brewers' yeast) is high, and it is maintained over a long period.

Clinical survey is important, for there are distinct variations and superimposed conditions to be found. Keratitis was rare in Nigeria, but common in Sierra Leone and apparently in P.O.W. camps. The Jamaican cases were fulminating. Beriberi is rare in Nigeria but common among ships' crews, on a diet of rice and salt fish, from Sierra Leone and Liberia.

A study of the various diets is a great assistance to the clinical diagnosis. In Nigeria retrobulbar neuritis was extremely common but in certain areas only, or under bad conditions which existed in some schools, chiefly boarding-schools, before the war. It was not seen in Nigeria or in those areas where yams or sweet potatoes or better-class cereals formed the staple carbohydrate. As early as 1933 I became convinced that manioc was the food cause, for the disease was essentially confined to the manioc-eaters. This view has been strongly upheld by Clark (1932, 1936), with the cyanogenetic theory, and his work might still be followed with advantage.

But in Jamaica manioc was replaced by sugarcane, in Sierra Leone and Spain (civil-war conditions) largely by rice, and in China and the Far East by rice. Where the rice was unpolished, or, as in P.O.W. camps, reinforced with barley and soya bean, there was least evidence of retrobulbar neuritis. A theory based on an exogenous toxin, therefore, can only be upheld if it can be proved to be common to all conditions. The theory of "spoiled rice" seems then to rest on rather slender grounds. There is an obvious alternative explanation—a theory based on an endogenous breakdown, as has been supported by Stannus (1940). It may be that certain foodstuffs do

But some cases, even of long duration, showed no change at all, and in others a frank primary atrophy was simulated, and more exceptionally optic neuritis. Dansey-Browning (1946), Rich (1946), and Dansey-Browning and Rich (1946) in their helpful and detailed clinical reports on released P.O.W. have made similar observations. To meet all considerations, a more general term may be required, and "nutritional optic neuropathy" (as has been suggested) is a reasonable one.

Landor and Pallister (1935) recognised the syndrome in a Malay prison, and included "dimness of vision" among the symptoms described. They found cod-liver oil useless. They were the first to use autoclaved marmite in the more general condition.

Jimenez Garcia (1940), in Spain, investigated a similar syndrome among Europeans during the civil war of 1936–39. He also described a retrobulbar neuritis. He believes the condition is a B_2-complex deficiency. This very important work has been insufficiently recognised in this country. There were many cases not only of retrobulbar neuritis but also of other effects of vitamin-B deficiency, and results of therapeutic trials. A study of the conditions in the siege of Madrid must bear valuable comparisons with the privations undergone in the Far East.

More recent contributions are those of Wilkinson and King (1944) in China, and of Dansey-Browning (1946), Rich (1946), Dansey-Browning and Rich (1946), Garland (1946), Ridley (1945), Spillane (1945), Spillane and Scott (1945), and R. E. Wright (1946) in this country on released P.O.W., besides the reports of the medical officers in charge of the P.O.W. and internee camps, to whom special acknowledgment has already been made.

TREATMENT

In Nigeria, from 1931 onwards, treatment in the early phases of this condition was generally successful (see figs. 1–3). The following is a typical example from many others quoted in published work.

Nov 13, 1937: an Ibo, aged 15 years, a thin depressed boy, with skin grey and dry, severe perlèche, dry scaly scrotum, raw red tongue, burning of the feet, and photophobia. Mother says he was cheerful before onset Vision defective February, 1937, severely so by March. In June he was forced to leave school, as he could only "listen in class" Mother a petty trader Diet· manioc 4 "cups" full daily, stockfish, red-palm oil, some green leaf, a small amount of meat occasionally, peppers, and salt Vision 1/60. Unable to read print. Both disks, optic neuritis. Treatment autoclaved marmite, one "cigarette tin" full weekly.

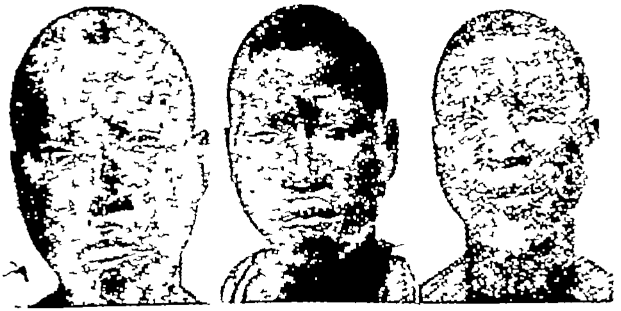
Nov 26: mouth and perlèche entirely healed, scrotum better. Vision 5/60 J.20 pt.

Dec. 12: 6/36 J 12 pt.

Dec 31: 6/12 J 8 pt. Skin shiny and bright, whole appearance altered, and patient delighted with progress.

Feb. 11, 1938: 6/6 J.1 pt.

If, however, treatment was delayed over six months, or perhaps a year, irreversibility became more manifest and increased with time. It appears to me that this factor has been the essential one which has counted so much among P.O.W. and not, as some would maintain, an irreversibility from the start of the illness.



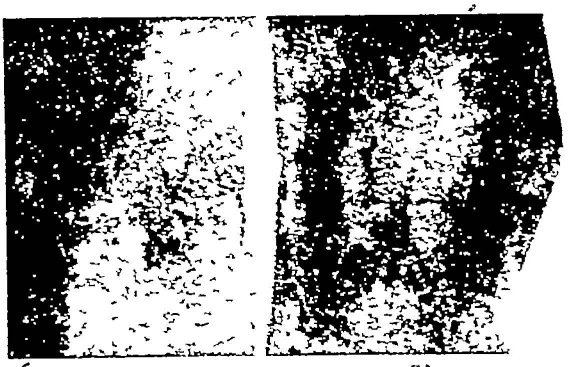
(a) (b) (c)

Fig. 1—"Joe," a Sierra Leonean, seen at Lagos in October, 1936, in conjunction with Dr. G. E. Dodds (now Senior Medical Officer, Nigeria): vision 5/60, 4/60, severe changes in optic nerves, and ataxia; history over two years; staple diet rice and manioc; (a) on first attendance; (b) after five days' treatment with marmite; (c) after eleven days' treatment. Visual condition was not followed up, as he was a member of a ship's crew in port only for that period.

With regard to prognosis, it was possible in Nigeria to follow up many cases for some years. Once the offending cause was removed, they did not worsen. This, it is felt, is of great importance so that patients may be reassured.

ÆTIOLOGY

The ætiology of nutritional retrobulbar neuritis in relationship to the more classical syndromes is still far from complete. I am satisfied, however, that it can be excluded from beriberi, though it can be associated therewith. The response I obtained with autoclaved yeast on the visual condition made this clear (Moore 1939). The investigations with thiamine in the P.O.W. camps surely brings further and impressive evidence against beriberi. In West Africa nearly all cases were either accompanied or preceded by hyporiboflavinosis (see also Hughes 1946). But it would not be safe to state that riboflavine deficiency caused the neural condition, for trials with riboflavine have never been sufficiently extended. Such tests are much more tedious and exacting in interpreting these findings than those directed to the more obvious skin and mouth conditions. Lack of riboflavine is no doubt an important causal factor, but other vitamins of the B complex, excluding thiamine, may also share in the cause, a view that has also been expressed by Stannus. The same is partly true for nicotinic acid, though there is more evidence that lack of this vitamin is not directly concerned. Experiences in P.O.W. camps appear also to support this view.



(a) (b)

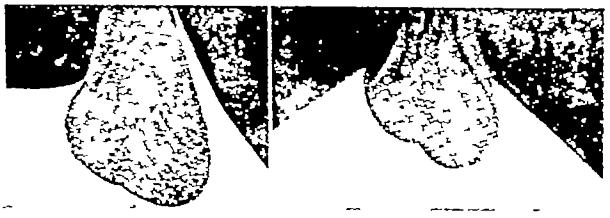
Fig. 2—Same case as fig. 1: rashes on flexor aspects of (a) arm, and (b) leg, on first attendance.

Therapeutic investigation, therefore, by exclusion trials has reached a definite but only intermediate stage. Treatment has yielded important results, provided it is begun early, the dosage (marmite or brewers' yeast) is high, and it is maintained over a long period.

Clinical survey is important, for there are distinct variations and superimposed conditions to be found. Keratitis was rare in Nigeria, but common in Sierra Leone and apparently in P.O.W. camps. The Jamaican cases were fulminating. Beriberi is rare in Nigeria but common among ships' crews, on a diet of rice and salt fish, from Sierra Leone and Liberia.

A study of the various diets is a great assistance to the clinical diagnosis. In Nigeria retrobulbar neuritis was extremely common but in certain areas only, or under bad conditions which existed in some schools, chiefly boarding-schools, before the war. It was not seen in Nigeria or in those areas where yams or sweet potatoes or better-class cereals formed the staple carbohydrate. As early as 1933 I became convinced that manioc was the food cause, for the disease was essentially confined to the manioc-eaters. This view has been strongly upheld by Clark (1932, 1936), with the cyanogenetic theory, and his work might still be followed with advantage.

But in Jamaica manioc was replaced by sugarcane, in Sierra Leone and Spain (civil-war conditions) largely by rice, and in China and the Far East by rice. Where the rice was unpolished, or, as in P.O.W. camps, reinforced with barley and soya bean, there was least evidence of retrobulbar neuritis A theory based on an exogenous toxin, therefore, can only be upheld if it can be proved to be common to all conditions. The theory of "spoiled rice" seems then to rest on rather slender grounds. There is an obvious alternative explanation—a theory based on an endogenous breakdown, as has been supported by Stannus (1940). It may be that certain foodstuffs do



(a) (b)

Fig 3—Same case as fig. 1: condition of scrotum and thighs (a) on first attendance, (b) after eleven days' treatment.

possess inhibitory toxic factors and also help to accelerate metabolic breakdown (e.g., cyanogenetic factors ; alcohol in secondary pellagra).

What has been established is that under conditions of duress or environmental restrictions, leading to an insufficiency in normal intake of protein and, to satisfy hunger, a relative overconsumption of energy foodstuffs poor not merely in vitamin B_1 but in all the B vitamins, nutritional retrobulbar neuritis has become common. Other syndromes may of course coexist, such as beriberi. And why say that rice can cause only beriberi, since in the light of our newer knowledge of the biochemistry of foodstuffs it is poor in all nutrients? (Moore 1942.)

It seems, then, that further and more exhaustive inquiries into the various diets on the lines of those which have already clarified some issues would be rich in results. The dietary records kept in the Far East will undoubtedly prove of extreme value.

PROPHYLAXIS

How do these conclusions affect the question of prevention? The fact that Europeans in the siege of Madrid and in the Far East have suffered from a nutritional eye defect has aroused world-wide interest, and rightly so ; but this is only one aspect of the picture.

It is known that, both in war and in peace, very many coloured people must be affected by one or other of these conditions. The world is now faced with acute famine, and naturally all that is possible is being done to meet this crisis. But it is certain that, where there is a gross dietary imbalance, and where carbohydrate foods of the type indicated above are almost the sole source of energy, and protein is deficient, then we can be certain that this visual complaint and the associated primary deficiency states must remain. It is not enough to ensure an adequate crop of rice or manioc ; we must also aim at a vast improvement in the variety of carbohydrate foods and of the diet as a whole and a rise in the economic standards of life. It has been ably argued that food yeast may prove a partial salvation. I believe that this must be only a temporary expedient. Perhaps these further experiences and the knowledge gained from them will do more than extend research by drawing attention to a condition or conditions which in time of peace ought to be completely or at least largely avoided.

ADDENDUM

Any survey of earlier work would be necessarily incomplete without reference to the following, recorded in Leitch's *Dietetics in Warm Climates :* " Winterbottom (1796), Physician to the Colony of Sierra Leone, drew attention to the observation by Bontius that among Javanese and Malays weakness of sight, said to be caused by rice, is removed by a better diet." Also to " Robert Clarke (1841), Surgeon to the Colony of Sierra Leone, who described ' ophthalmia and paralytic complaints with chronic inflammation of the mouth ' in the prison, and the diet was said to be ' one quart of rice and a quarter of a gill of salt per day.' "

Also the account referred to by H. H. Scott (1918) of H. H. Strachan (1888, 1897) (who, though he believed the cause malarial, gave a most observant account of his visual findings and the sore-mouth syndrome).

MEDICAL EDUCATION IN QUEENSLAND

FROM OUR AUSTRALIAN CORRESPONDENT

A REVIEW of medical training at the University of Queensland has resulted in a new curriculum which will come into operation in 1947. The course will last six years, the academic part occupying five years, and the final year being spent in attendance or residence at an approved hospital. The final examinations will be held at the end of the sixth year.

The objectives of the curriculum are :

In the practice of general medicine and surgery *specialism should be carefully avoided.*

Development of intelligence, initiative, and judgment.—It is an anachronism for a student on graduation to rely on such facts as he has managed to memorise, without having the ability to think and act for himself. Scientific direction must replace empiricism.

Training in acceptance of professional responsibilities.—Graduates must have the faculty of judgment developed by their medical training.

Training in moral responsibility.—The spirit of the Hippocratic oath is much more necessary today than it was in the mystic era which saw its birth.

A balanced education.—Equilibrium must be achieved in the face of clamour for the good practical man on the one hand, and a lament for the passing of the classical education on the other. The changing nature of this equilibrium should be recognised, and changes made gradually.

Promotion of student health.—The practitioner of medicine must be an apostle of health, and positive health practices would have an educational as well as a physical value.

Training in citizenship.—The relationship between the practitioner and the community is an essential aspect of medical practice.

A teacher, as well as having a sound knowledge, should be able to inspire the student with a love of learning in general and of his own subject in particular; he should have a positive character, high in moral principles ; he should have, or should develop, the art of teaching ; and he should be critical of himself and have a balanced outlook. The teacher's main responsibilities should be :

To make facts available in convenient form.—By appropriate stages, education in the true sense must be substituted for teaching in the narrow sense.

To train students in judgment upon facts.—Facts are mainly valuable for the enrichment of concept. The battle-training of judgment should replace much of the squad drill of facts.

To train students in the application of theory to practice.—Practical demonstration is preferable to didactic instruction.

To train students in manual skill.—Delight in performance is a necessary attitude of mind prerequisite to the development of manual skill.

To encourage the development of character and a wide education.

To correlate subjects with one another.—Each subject must be linked with what went before, what is coming after, and what is being taught at the same time.

For the matriculation, English, physics, chemistry, mathematics, and one language are essential. In the first year much of the general physics and chemistry will b

omitted. Physics will be restricted to a revision and unification of the matriculation standard and the study of the physical phenomena important to the understanding, investigation, and control of living material. Chemistry similarly will be revised and unified up to matriculation standard, and will provide the fundamentals of physical and organic chemistry necessary for the understanding of physiology. The first year will include general biology, comparative anatomy, general human anatomy, developmental anatomy and histology, and medical zoology. The second year will cover regional, systematic, and developmental anatomy, systematic physiology, integrative physiology, and neurology. The third year will deal with clinical anatomy and physiology, general and special pathology, pharmacology, normal psychology, clinical methods, materia medica and pharmacy, bacteriology, and hæmatology. The fourth year will cover systematic medicine and surgery, social medicine, and obstetrics. In the fifth year the students will work in clinical groups, and will also study and practise clinical anatomy and pathology, surgical pathology, and social medicine. The special subjects will be allotted only two hours per week. Two weeks' full time must be spent in residence at an obstetric hospital. In the sixth year ten weeks' residence will be undertaken in (i) a surgical and (ii) a medical division of a general hospital; (iii) a women's hospital; and (iv) a children's hospital.

Students should be initially selected on the grounds of character and physical standard as well as by examination. During the course, a third of the marks should be allotted for work done during the year as shown by practical work, seminars, and quiz classes. Greater importance should be attached to knowledge of principles and their application than to memorised facts. Manual ability should be considered in the assessment of qualification.

In the preparation of this curriculum much valuable guidance was derived from the report of the Royal College of Physicians of London. The Goodenough report, which appeared after the curriculum was formulated, was a helpful reinforcement in securing administrative approval.

RESEARCH ON AGEING

CONFERENCE IN LONDON

ON July 16 a conference was held in London by the British branch of the Club for Research on Ageing. The meeting was attended by delegates of the European branches and by other guests interested in the subject. Lord Nuffield was elected hon. president of the conference, and Sir Francis Fraser chairman.

Sir **FRANCIS FRASER** described the rôle of clinical research on old age. This, he said, was the most difficult of all fields of research, since there were always so many uncontrolled factors. Quick results were not to be expected: one must think in terms of long-continued and laborious research. Pathological conditions were generally present in addition to old age, and it was difficult to differentiate between them. He concluded that clinical research on physiological ageing was practically impossible, and it was better for clinicians to concentrate on studying primarily the pathological conditions.

SCOPE OF THE PROBLEM

Prof. F. A. E. **CREW**, F.R.S., gave an account of recent work in Scotland on the sociological problems of an ageing population. The current figures for births, deaths, and marriages appeared satisfactory on the surface, but when examined more carefully the present population trend showed a most disquieting increase in the proportion over 65 years of age. Since industrial capacity diminished after 35 there was a danger of the old becoming a burden on the younger members of the community. He emphasised the need for closer collaboration between clinical investigators and those working on population research. The real problem of gerontology was "not how to give years to life, but life to years."

Dr. **MACDONALD CRITCHLEY** called for further research on the nervous system in normal ageing as well as the associated pathological conditions; he described a number of possible schemes of research in neurogerontology.

Dr. V. **KORENCHEVSKY** defined the aim of gerontology as not merely to achieve a longer life but also a stronger one. Since ageing starts at a very early age, the whole life-span, and even the development of the fœtus, must be studied. Attempts at rejuvenation by such methods as Voronoff's glandular grafts, hormones, or Bogomoletz's serum had proved unsatisfactory, since they achieved only temporary stimulation; the aim must be to discover and remove the causes of premature ageing and not to stimulate degenerated tissues. He outlined five conditions required for international and local organisation of research on ageing.

Prof. F. C. **BARTLETT**, F.R.S., considered that the effects of ageing on performance could be compared with the effects of other factors, such as extremes of heat, humidity, and noise. Each of these factors produced an increased liability to fatigue, which could be measured in a number of ways. New methods developed during the war for the study of skill and fatigue in air pilots might be applicable.

Prof. G. R. **CAMERON**, F.R.S., emphasised the need for quantitative research on the effects of ageing on the blood-vessels of the brain: there was scope for the employment of many new techniques. Lord **NUFFIELD** said he could not understand how ageing could begin in early childhood, since the athletic performance of a child went on improving up to the age of 15. Dr. **KORENCHEVSKY** and Mr. **JOHN HAMMOND**, F.R.S., pointed out that different organs developed at different ages: brain and bone had priority at an early age and muscle developed only later. Prof. M. J. **STEWART** wanted research to be carried out on blood changes in old age; it was striking that many old people died of pneumonia because their blood failed to respond as vigorously as that of young people to the toxins of the pneumococcus.

IMPORTANCE OF STATISTICS

Dr. **DEREK RICHTER** urged the need for more accurate statistics on causes of death. The present figures were unreliable as permission for a necropsy was often refused. The public must be educated to realise the importance and value of post-mortem examinations. The development of gerontology as a science could be seen in the two editions of Cowdry's book on ageing. The first edition was made up largely of speculation and poetry; the second contained less poetry and more facts, figures, tables, and measurements. Clinical science could help by providing greater precision in the measurement of the factors concerned.

Dr. **LETITIA FAIRFIELD** deplored the way in which the chronic sick and aged were despised by the teaching hospitals and thrust on the public authorities. Medical science had relieved many of the worst miseries of old age, such as bladder and prostate troubles; but senile dementia was a social problem of increasing urgency. Was it right that healthy young women, who should be bringing up children in their own homes, were now engaged in washing dirty linen in wards filled with wet and dirty senile dements?

The guests from Sweden, Denmark, Holland, and France reviewed the work on ageing that was in progress in their respective countries. Dr. W. B. **PURCHASE**, speaking as a coroner, agreed that the present statistics were unreliable, and said he could provide each year reliable figures for some two thousand cases on which necropsies were carried out. Professor **CREW** said he was anxious to close with Dr. Purchase's offer. Dr. **FAIRFIELD** considered that the conspiracy among general practitioners to avoid putting cancer on death certificates might be sufficient to result in a significant statistical error.

The morning session was concluded by the passing of five resolutions, proposed by Dr. **KORENCHEVSKY**, expressing the views of the conference on the requirements for the rapid advance of gerontology. These included international coöperation, for which purpose the club was founded; establishment of permanent institutes for research on ageing; and the provision of ample funds to secure these facilities.

SEX HORMONES AND AGEING

At the afternoon session Mr. P. Williams, d.sc., read a paper for Prof. E. C. Dodds, f.r.s., on the significance of androgen and œstrogen excretion in the urine in relation to ageing. The tendency to cancer of the prostate was considerably affected by the sex-hormone balance as shown by experiments on castration and by the effects of administering stilbœstrol in the male. There was a need for further quantitative data on all age-groups.

Professor Crew pointed out that the male infant had a much poorer chance of survival than the female. A male infant with bronchopneumonia was thus suffering from two conditions: (1) bronchopneumonia and (2) maleness. Could we use sex-hormone preparations to transform temporarily a male infant into a female to get over this disadvantage?

Mr. Hammond described recent work at Cambridge on the ageing of the fœtus in rabbits and sheep. The chronological age must be differentiated from the physiological age, as measured by the size, the ossification of the bones, and development of the heat-regulating centres. The physiological ageing of the fœtus could be varied experimentally by controlling the size of the litter and the nutrition of the mother. He suggested that similar factors might operate in the return to an infantile condition in old age.

Prof. J. B. Duguid put forward a new theory of the thickening of arteries in atherosclerosis. He felt that we had been misled by the teachings of Virchow. The thickening did not come from within the artery walls; it was due to the organisation of successive layers of fibrin deposited on the intima. The difference was fundamental, since the primary cause of the disease was in the blood rather than in the vessels. Professor Cameron asked how this concept could account for lipoids in atheromatous plaques. If the arterial narrowing was due to encrustation with fibrin from without, why did not the veins get narrowed in the same way? Professor Duguid felt the relation of lipoid changes to atheroma was not fully understood. The veins did not get narrowed because, when they were thrombosed, the whole vein became blocked, whereas in an artery the vessel was cleared by the rapid flow of the blood.

Dr. Korenchevsky gave an account of experiments on the artificial premature "climacteric," its effects on the process of ageing in female rats, and the influence on this process of androgenic, œstrogenic, and thyroid hormones. Ovariectomy hastened ageing of rats. The combination of androgenic, œstrogenic, and thyroid hormones produced an apparent "anti-ageing" effect, as judged by the weight and histological appearances of some vital organs; but this might be merely a temporary stimulation of ageing organs. Prolonged treatment might be followed by collapse, since the stimulants did not remove the causes of ageing.

PSYCHOLOGICAL FINDINGS

Dr. W. Stephenson read a paper for Dr. P. E. Vernon on the effects of vitamins on the mental state of senile patients at Tooting Bec Hospital. It was concluded that large amounts of vitamins exerted little effect on psychological ageing when the diet contained sufficient of these compounds. Dr. Stephenson described also some work of his own in which addition of vitamins to a diet previously deficient in these substances had been followed by improvement in the mental capacity of senile subjects. Professor Bartlett criticised the use of psychometric tests in these experiments; he held that the performance of such a test was not characteristic of senile subjects. It would be better to measure the kind of things that old people normally enjoyed doing.

Dr. Richter described an investigation on the biochemical changes in ageing. The results indicated that the mental and the physical deterioration of ageing were different processes that could be defined by their biochemical accompaniments. In advanced physical senility there were blood changes which were distinct from the changes normally occurring in old age; the changes associated with senile dementia were different again. Senility was not a simple entity, but was made up of a series of pathological processes, which should be more clearly defined by further work. Ignorance of the biochemical changes in the tissues of the ageing left a big gap in the knowledge of the subject. Muc public money was now being spent on palliative measure such as homes for old people: there was an urgen need for the allocation of more money to preventiv measures, which meant research.

Dr. J. H. Smyly gave an account of the metho developed by him for assessing physical fitness in ol men. These included exercise-tolerance tests, as measure by pulse-rate and oxygen consumption. The usu methods might be dangerous for old people.

Professor Crew, in summing up, said that the propor tion of old people in the population was increasing, an gerontology was therefore a science of growing socia importance. Geriatrics must also come to occupy place in medicine not less important than that o pædiatrics today. He recommended the formation of permanent international congress committee, to organis international gerontological congresses.

CANADIAN MEDICAL ASSOCIATION'S MEETING

FROM OUR CANADIAN CORRESPONDENT

The 77th annual meeting of the association was hel in Banff, Alberta, from June 10 to 15. The Britis Columbia branch sponsored the convention, but th Vancouver hotels were already full; so the choice fe on Banff, with its great C.P.R. hotel capable of taking thousand guests, and another large hotel 40 miles awa at Lake Louise. Every guest-house and motor camp i the neighbourhood was prepared for those who could no be cared for by the hotels.

No fewer than 889 doctors registered, but only 3 guest came from Great Britain—Sir Stewart Duke-Elder, Si Leonard Parsons (who gave the Blackader lecture o pædiatrics), and Dr. Donald Paterson. We hope tha the account they will give may encourage their colleague at home to visit the Canadian Medical Association th next time it holds its annual meeting in the West.

At the ceremonial evening Dr. Wallace Wilson (Vancouver) was installed as the new president. The next morning brought the valedictory address of the retirin president, Dr. Gérin Lajoie, of Montreal; with nationa unity in social and scientific endeavour as its theme, thi was Gallic oratory at its best.

The exhibition of works of art by members of the association was visited by everybody. The prize for a painting in oils went to Dr. R. C. Riley, a pathologist from Calgary; the prize was a bas-relief portrait of the late Sir Frederick Banting. The photographic section included the work of a score of experts, all of whom are in practice.

Everybody had a chance to see mountains and the lakes away up near the snow line. The time was too early for the poppies, but the glacier and the snow-capped mountains made a perfect setting for the cold blue jewel of Lake Louise. Lake Moraine is several hundred feet higher than Louise, and the road skirts the mountains, with towering peaks on one side and a fearsome precipice on the other; from it, the "ten peaks" came into perfect view. Nearer town was the ski-run. Only skilled and pioneer experts are allowed to use it in the winter; they climb for five hours and come down in seventy seconds.

The great mass of Mt. Eisenhower was seen best from the train, but came into view among the other peaks as the road spiralled upwards. The Albertans have not entirely discarded its old name of Castle Mountain but combine it in its new identity by referring to "Castle Eisenhower," which perhaps enhances Canada's compliment to the generalissimo. There may be more splendid scenery in the world, but medical conventions are not usual in national parks a mile above sea-level, with a regiment of rocky snow-clad mountain peaks arrayed against the skyline.

". . . The idea that the scientific and inventive mind is necessarily antagonistic to the merciful heart is as degrading to knowledge as it is untrue of the virtue of goodness. The gap between application of the two qualities is due to the selfish sides of human nature, and not to the increased power and supplies which knowledge provides for the primary needs of life."—Sir Richard Gregory, f.r.s., *Nature*, *Aug. 3, p. 151.*

Medicine and the Law

Pensions Appeals

CONTROVERSY over the Serviceman's right to a pension ntinues. Parliament may evolve a formula, but the o sides naturally attach most emphasis to those words ich best favour their own interpretation. The Service- n presses for the logical principle that, if the State und him "fit to serve," his subsequent disabilities st make him "fit for pension." The Ministry of nsions declares that it cannot accept this principle d has no power to go outside the royal warrant which verns the grant of pensions. Questions in Parliament ve made us familiar with the case of a man who, for stance, has his leg amputated while serving in the rces but is refused pension on the ground that the sease from which he is suffering is not attributable to, r aggravated by, war service. The Ministry has to ove beyond reasonable doubt that the Service condi- ns played no part in producing the disease; if it fails discharge this onus, the pension must be paid.

To some interesting judgments delivered by Mr. stice Denning in English litigation we must add the mments of the Court of Session in Edinburgh during Scottish appeal decided on July 19. The Ministry, it ems, had been relying on the fact that the claimant d a predisposition to the disease or an inherent consti- tional tendency thereto. The Scottish court made ht of predisposition. It only meant, said Lord Cooper, at, if the patient were exposed to the conditions, own or unknown, the disease would find in his constitu- n congenial soil in which to develop. The court was unable to see the relevance of such a consideration" -surely a triumph of judicial detachment. Then followed curious observation. Lord Cooper took note that, in ree out of the sixteen pensions appeals before the urt, the legal chairman had been in the minority on e issue whether the Minister had discharged beyond asonable doubt the onus resting upon him. The nsions appeal tribunal is competent to decide by a ajority, but "it appears to the court that, when the estion is the sufficiency of evidence to discharge such n onus, and when express injunction has been laid upon e tribunal to give the claimant the benefit of any asonable doubt, only powerful considerations could stify the medical and Service members in outvoting e legal chairman." The opinions of learned judges are titled to the greatest respect, but this obiter dictum nnot be accepted without protest. Parliament has nstituted a pensions appeal tribunal consisting of a gal, a medical, and a Service member, with the legal ember acting as chairman. The courts really must not nstrue the enactment as meaning a tribunal of one gal member with two assessors.

Meanwhile the Minister of Pensions has had to consider e situation arising out of the recent judgments. He formed the House of Commons on July 25 that, to move any sense of injustice, he was prepared to receive pplications from claimants whose appeals had been isallowed by a tribunal before the end of July and who ere of opinion that their claims would have succeeded the tribunal had happened to consider them after the ourts had expressed the views now promulgated. The inistry will examine the applications. If satisfied that he case is covered by the recent judgments, it will pay he pension at once. If it thinks the claim should still e rejected, the applicant will be able to take his case efore a new special arbitration tribunal outside the ramework of the Pensions Appeal Tribunal Act. The ecisions of this new type of super-tribunal must be ccepted as final. Its constitution will be similar to that f the existing statutory tribunal. It is hard to see what ore the Ministry could have done in the difficulties hich have arisen.

In England Now

A Running Commentary by Peripatetic Correspondents

FOR fifty-one weeks in the year I am, as a medical officer of health, a man of moderate dignity. During the remaining week I attend a conference, accompanied by the chairman and one or two members of the committee which controls the health activities of my urban community, and for several dreadful days become the slave of circumstance, a mere puppet at the call of those in authority. There is no escape. I live with them in the same hotel; we go together to the conference; when they get bored with the speakers I join them for a coffee, or, if we are lucky, a beer.

This personal grouse is, of course, of no general importance; but when one considers the situation multiplied by the scores of other medical officers in the same kind of predicament, an element of pathos creeps into the picture. For instance, I see another medical officer, an old colleague whose friendship I value. "Hullo, Frank," I shout. He smiles and signals cryptically. I understand; and we pass on; for he, too, has his chairman; he, too, is for one week in the year a miserable flunky.

This is the tragedy of mixed conferences, the eternal polarity of oil and water, the east and west which never meet unless in the neutrality of mediocrity. It may well be that when doctors get together they talk shop; but from their intellectual and social contacts is born a great deal of good. Here is gained a refreshment of mind; here is found a new peace because one hears of another's difficulties; here is added the needed strength to return to homely problems with a fresh hopefulness. But this promised land of a conference is always marred by the different kinds of pilgrims who yearly congregate under the banner of health: professional officials with their committee members; local-authority vassals with their lords and masters.

I find it difficult to suggest a solution. Undoubtedly the dancers and those who pipe the tune must meet at times on common ground; but let the intercourse be sweetened by brevity. I am now wondering if this personal experience of a health conference is a grim presage of things to come, when we are all public servants with personalities rounded off by the emery-wheel of officialdom and lay control. I hope that as doctors we shall ever maintain a pride in our own professional culture; that in our necessary concourse with the controlling representatives of the public and the State we shall never lose the sense of our high calling; and that, however they may judge us, we shall preserve our freedom to think well of ourselves and be worthy of the thought that inspires.

* * *

You probably don't realise what an organisation lies behind taking the Girls' Club to the Tower of London. First of all my wife had to discover the fare and the time taken on the journey so that their mothers could be told what time they would be home. Then a detailed reconnaissance had to be made, so that at any point on the way we could direct them to the nearest lavatory (small girls seem to have so much less initiative in these matters than small boys). My job was more localised—to find out the cost of admission, the best time to go, and the possibilities of a guide. The warder I spoke to was extremely helpful and obviously an artist. He anxiously inquired their ages, and was pleased that they were about fourteen. "That's the best age," he said. "They're young enough to be enthusiastic and not too young to Understand the Tower." The nearest Lyons had to be approached with a request for large-scale tea; we know from previous unhappy experience that some softening-up is necessary before invasion. A letter had to be sent to the Governor to book a guide. It had to be explained to the girls that meeting at two-fifteen meant that no lunch need be brought and that no letters of permission from their mothers were needed. No, nor pyjamas. Yes, you may bring sweets.

The journey by underground was uneventful—by club standards. The doors were unfortunately hand-operated, but nobody fell out irretrievably. The more sophisticated ones whistled at the men on the platform and the agile types swung up and down the carriage on the straps. Edie stood on one leg in an attempt to master the rocking of the train and naturally fell flat on her face. Fourteen-year-old Doreen surveyed the prostrate thirteen-year-old at her feet with great distaste and said to the carriage in general: "They do show you up, don't they?" Later, Doreen began to auction a 'Kirbigrip' but the bidding had only reached two slides and a toffee when we had to get out.

At the gate we demanded a guide and the warder asked if we had a paper. Edie timidly offered him a "True Romances" and was gently waved aside. How do they choose the warders? It says in the catalogue that they are chosen from "the most deserving N.C.O.'s in the Army," but surely they have a voice test as well? And are they trained to throw their cloaks open with such nonchalance, or is that also an inborn ability? Our man handed out murders, executions, escapes, dates, kings, queens, ghost-stories, and facts with great charm and assurance, and there were soon several dozen people round us. For good measure he added odd facts about the history of London and mentioned Smithfield, where "people were burnt for any form of religion."

We were left to inspect the White, Beauchamp, and Bloody towers by ourselves, having been warned not to miss the inscriptions carved by "hapless prisoners." Soon after this I saw Rose gazing in sympathetic horror at the pencilled signature of John West, Boston, Mass. They liked the armour and felt sorry for the horses. "Is that a real body?" "Oh, Syl*vie*, you are *silly*." "Oh look! There's some armour in Technicolor." Doreen was fascinated by the block and axe: "I bet it feels funny." When we collected them outside there were three missing, inevitably. Equally inevitably, one of them was Edie. I found them listening in rapt attention to a warder who was giving them a private talk on the nicer points of armoury. He apologised sheepishly when I arrived, but I left them to it.

Edie was very quiet on the way home. I think she was Anne Boleyn on the way to the scaffold.

* * *

When I volunteered to help with the bottling of fruit, little did I realise how much of a busman's holiday it was going to be. How like the sterilising-room is the kitchen during these episodes, with the oven as the autoclave and the kettle as the steriliser. The fruit goes into the bottles like the swabs into the drums, and the bottles are scalded just as bowls are flamed. Our womenfolk are little behind us in using the aseptic technique.

The principle is simple. The fruit is sterilised by spending an hour in the oven; and then, after boiling water has been added to the top and running over, the bottle is sealed with a rubber washer and a glass top. As the bottle cools, the cap is sucked on, and a vacuum is formed, excluding all bacteria until the day for opening arrives. This cooling-time is the critical one of the whole process, for a faulty cap will let in air and all the vacuum is lost. It cannot be hurried and at least twelve hours must pass before testing. What hours of anxiety must have been spent in the past!

Now this is where I claim to have made an important advance in technique. By one simple step, within fifteen minutes of sealing, the offending bottles can be picked out, refilled, and resealed. Auscultation of the bottles is the secret. As the air sneaks in it makes a most delightful sibilant hiss that is quite distinctive through the stethoscope. One cannot miss it, and with perfect confidence and an authoritative air one can diagnose the successes from the failures.

Any man can do the unskilled task of topping and tailing gooseberries, but we in the medical profession can rise above that. Auscultation is a specialised game, and who is better qualified to do it than the doctor's wife's husband?

As deputy public vaccinator enacting the instructions in the fourth schedule I feel as one would who was caught by one foot in the fourth dimension. The fees are paid over the top of the bureau eventually, but it never works out as planned in Form G.P.H.5. The mental ardour I put into computing the payment in 17 different categories is, as I know from R.A.F. experience, worthy of a Pathfinder navigator. I waste precious minutes wondering why the vaccination of a child who, five days after the puncture, was transferred to an unknown address 300 miles away should be worth 4*s*. 2*d*. when a Successful Vacc. is worth 6*s*. 0*d*. and an Unsuccessful Vacc. (Patient's
House, First Person) is worth nothing; two visits
made in each case and the burnt petrol smells the sa

Letters to the Editor

RELEASE OF SPECIALISTS

SIR,—Once more Sir Ernest Graham-Little has proved mself the champion of the Services medical officer asking the Secretary of State for War whether he as aware of the wastage of specialist man-power in ie Forces, in particular of orthopædic and surgical ecialists (*Lancet*, Aug. 10, p. 217).

Mr. J. J. Lawson's reply that he was not aware of any astage of specialists in the Army will strain the credulity quite a proportion of surgical specialists at present rving. To meet surgical specialists who are "supernmerary to establishment" or are "attached to a ommand specialist pool" is not uncommon; those so aced are not necessarily employed in their specialty nd, as often as not, are employed as general-duty ficers, performing such duties, in the majority of cases -let it redound to their credit—with a good will.

The Army is rapidly becoming a "younger army," nd the proportion of young conscripts and recruits increasing. For this reason surgical procedures are ss frequently indicated and are mostly confined to the pair of hernia (admittedly never lightly to be under- ken) and to the treatment of varicose veins and hydrocele. The remainder comprise minor surgical rocedures well within the experience of a graduate 2–3 years' standing. Army surgical practice is istinctly limited in its scope, for several reasons: in ie first place, it is predominantly directed towards the ale; secondly, the Army comprises a section of the opulation in which surgical emergencies are bound be relatively infrequent; thirdly, most surgical rocedures practised today are of the type already escribed—surely a surgeon's scope should be wider than is even in these days of specialism; and fourthly, wing to the examination of the conscript and recruit y a medical board whose standards are now higher, ie men at present entering the Army are, in the main, ealthy.

Mr. Lawson's contention that he is not prepared single out *Army-trained specialists* (my italics) for ly release as it would break down the basis of release age-and-service group priority does not bear examina- on. In the R.A.M.C. alone, general-duty officers have een released in groups at least ten in advance of ecialists and therefore the Secretary of State for War ould not be creating a precedent by "singling out" rmy-trained specialists for early release. The basis as already been broken. Does this statement then iggest that he is prepared to single out for release *lly qualified* specialists?

Only two days ago, the *Times* (Aug. 8, p. 2) published ie releases from the Forces for the period Oct. 1–ec. 31, 1946, announced by the Minister of Labour nd National Service in which the officer releases from ie Army for that period consist of age-and-service roups 40–46. Can the Secretary of State for War aintain that the basis of release by age-and-service roup priority has not been violated, when the declared leases for R.A.M.C. specialists by Sept. 30, 1946, onsist of groups up to and including group 35? At the ime of writing, no policy for the release of specialists yond group 35 has yet been declared by the War Office, lthough the Central Medical War Committee in reply Aug. 7) to a request for information on this matter ave kindly ascertained that "it *is hoped* (my italics) hat the release programme for the period Oct. 1–Dec. 31 ill be published within the next few days."

W. R. BLACK
Major R.A.M.C.

TREATMENT OF MENINGITIS

SIR,—The most retrograde step in therapy since the ntroduction of penicillin has surely been its use ntrathecally in cases of nontraumatic meningitis. It salutary, therefore, to learn from the article by Sir Hugh Cairns and his colleagues (Aug. 3) that streptoycin used intrathecally was largely ineffective and aused a high incidence of unfavourable reactions. When streptomycin becomes available in this country s systemic use will be of the greatest value; may its intrathecal use be confined to those traumatic cases rightly under the care of the neurosurgeons.

There was a time when we treated meningitis in children by repeated punctures—lumbar, cisternal, and (in infants) ventricular—injecting antimeningococcal serum and washing it through. If the child recovered it was felt that a great therapeutic victory had been won. However, it was later found that just as good results were obtained if the theca was left severely alone after doing a single lumbar puncture for diagnostic purposes and giving large doses of antiserum intravenously and intramuscularly. With the advent of the sulphonamides this impression was strengthened and confirmed. Full doses of a sulphonamide, sedation, hypertonic rectal salines, and quiet, produced the best results.

With the advent of penicillin, intrathecal therapy has come into fashion again. I believe that any case which has recovered after intrathecal therapy has recovered in spite of this interference and not because of it. Sterilisation of the cerebrospinal fluid will not necessarily cure a child with meningitis, nor is recovery directly dependent on the sulphonamide or antibiotic content of the spinal fluid. Meningitis is a systemic disease and intensive systemic therapy is the best form of treatment.

Warwick. WILFRID F. GAISFORD.

PROSTATIC CANCER

SIR,—I have read Dr. Gutmann's letter on adrenalectomy for prostatic cancer (Aug. 3) with great interest. Like him, I have considered attacking the pituitary directly by radiation. After consideration, however, it seemed best to avoid over-inhibition of the pituitary by periodic administration of œstrogens. For some two years, at the Meath Hospital, Dublin, we have been giving œstrogens for alternate weeks only, hoping thus not to excite the adrenals into compensatory overproduction of androgens.

With such a small and short experience it is not possible to make any definite statement or claim. It can be said, however, that from the clinical point of view the intermittent administration of the œstrogens seems, so far, to be as effective as the continuous.

Dublin. T. J. D. LANE.

C.CM. OR MILLILITRE?

SIR,—Dr. Beaumont in his letter of Aug. 3 is so concerned with what he considers to be the impropriety of converting cubic centimetres into millilitres that he seems to have lost sight of the subject of my first letter, the fact that the millilitre and not the cubic centimetre is the correct subdivision of the litre and that the cubic centimetre should never be used as an alternative to the millilitre with which it has no connexion.

He does not agree that my suggestion to convert cubic centimetres into millilitres is a valid procedure for ordinary medical purposes. In this he is not supported by the *British Pharmacopœia* (1932) which states (p. 639) that the millilitre (not the cubic centimetre) is the proper subdivision of the litre and gives a conversion-equivalent which justifies my advice.

Dr. Beaumont refers to the predicament in which he finds himself of having to use a syringe graduated in cubic centimetres, but apparently does nothing about it beyond saying that he likes to call a cubic centimetre a cubic centimetre. For himself he can do as he likes, but for the sake of others he should convert into millilitres in deference to the official nomenclature of the *British Pharmacopœia* and the fundamental reasons on which that nomenclature is based.

If he persists in an outmoded and incorrect nomenclature there is nothing more to be said except perhaps to add that his self-made difficulties could be resolved if he and other clinicians arranged with manufacturers to graduate syringes in millilitres. Scientific workers have long ago done this for their measures of capacity. It is a reproach to clinicians that they lag behind.

London, S.W.7. J. M. HAMILL.

PS.—Since writing the above I have seen a pamphlet on Penicillin Treatment by Dr. Beaumont and Dr. Palmer. In this pamphlet millilitres are used throughout even when measuring from a syringe. I congratulate Dr. Beaumont on his adoption of the correct nomenclature.—J. M. H.

THE NATIONAL LOAF

SIR,—THE LANCET took a brave share during the war in the battle for a pure and nutritious national loaf, a battle which succeeded after three years' struggle (1939–42) in compelling the Ministry of Food at long last to supersede the 70 % extraction of the national loaf by an 85 % extraction from April, 1942. The "discovery" (of dubious sanction) that high-extraction flour was rendered positively dangerous for human consumption by the presence in the germ of a constituent (phytic acid) which militated against the assimilation of "calcium" was the springboard for the decision taken by the Ministry of Food to add chalk to the national flour as a means of combating this supposed ill effect. This addition was hotly criticised in your columns and I submit that the addition has lost authority in the intervening years. The whole-wheat grain has formed the staple diet of the human race for immemorial ages ; it is surely repugnant alike to common sense and to universal experience to pretend, as a certain small section of opinion contends, that high-extraction flour for the national bread unless "fortified" by chalk is positively mischievous.

It is to be noted, incidentally, that the Ministry of Food in its communications to the public and even in parliamentary answers has consistently avoided the use of the word "chalk" to describe this addition ; it has been variously camouflaged as "calcium," which is a misdescription, and as "creta," which is its Latin equivalent, unintelligible to the great mass of the public who are thus, I submit, deliberately misled.

Alterations in the composition of the national flour have been made in the last five years with bewildering frequency, mostly in the form of secret instructions to controlled millers. The community contributes the not inconsiderable sum of £35 million per annum as a subsidy for bread alone ; it is surely entitled to be fully informed, in intelligible language, what it is eating from time to time. I accordingly, in a parliamentary question, requested the Minister to give an undertaking that the public should be immediately informed of any change in the composition of national flour, and the Minister gave me that undertaking (*Hansard*, July 8, 1946). On July 24 the Ministry of Food issued to controlled millers a circular headed "confidential, not for publication" which required them to double the quota of chalk, camouflaged as "calcium," in the national flour. On July 29 the Minister received a protest from me in the form of a parliamentary question, pointing out that this undertaking had not been observed, and on the following day the Minister saw fit to inform the press of the alteration in composition.

The practice began in 1940, and has continued ever since, of making extraneous additions to the national flour supposed to "reinforce" its value, until the Ministry's "prescription" for national bread reads rather like a description of a patent medicine. This tendency was severely criticised (*Times*, Oct. 26, 1940) by the late Sir William Bragg, perhaps the most famous president of the Royal Society in our times. The words he used then are as pertinent now as when they were uttered. He wrote :

> "Science is built on the accumulation of experiences and every scientist knows that he must not base his conclusions only on the last few experiments in the laboratory. . . . Practice is based on the experiments of innumerable years . . . the knowledge thus gained in ages of trial and error are all of value ; they are not to be thrown aside in favour of the last galvanometer reading. . . . In this *matter of food the scientist is at the present time insisting that certain old ways are best* . . ."

and he went on to point out that the nutrition of the nations reached its highest level "when milk and vegetables, fruit and *whole-meal* bread (the italics are mine) were commonly consumed."

London, W.1. E. GRAHAM-LITTLE.

DEMOCRATIC NURSING

SIR,—The excellent article by Mr. Sol. M. Cohen contains many suggestions which, if practised, would be of inestimable benefit to all working in hospitals.

However the idea of a full democratic development must extend, too, to those who lay down rules for administrators. The following is an extract from t duties of a matron enclosed with an application form f a recently advertised vacancy :

> . . . She shall inspect all the wards each day and th also make similar visits at uncertain hours not less o than once weekly during the night . . .

The suggestion contained in this paragraph is t neither the ward sisters nor those in charge at are to be trusted in carrying out their normal duti Until nurses in charge of wards are given a position responsibility and trust, comparable to that of a physici or surgeon in charge of wards, ward sisters' posts w remain unattractive.

I recently questioned 50 nurses on completion of th State examinations ; less than 10 % of these girls desir to remain in general hospitals or to become ward siste This is a very serious reflection on present attitudes both municipal and voluntary hospitals. "Lip servic on the value of ward sisters will not suffice.

Central Middlesex County Hospital, HORACE JOULES
London, N.W.10.

MALE NURSES

SIR,—To the constructive observations of Mr. H. J. Atkins (July 13, p. 63) might be added the comm that enough use is not yet made of the trained gen male nurse. *He is in fact unknown to the aver* general hospital, and, as the *Male Nurses' Jour* recently said, "up to the recent war, some of the medi profession had never heard of a male S.R.N."

Eighteen to twenty years ago there were only training schools for male student nurses ; today th are 51, with others affiliated, and 1 for training infectious diseases. Nevertheless, further numbers mi still be trained and employed, particularly now wh valuable potential nurses are being demobilised from Forces.

The male nurse is almost always keen, and unl some female nurses he remains permanently in profession, which he regards as his life's work. ethical standard is no less rigid than that of the qu fied practitioner.

A new spirit prevails nowadays. The "starc dictator" is gradually vanishing, and greater relia is being placed on the team spirit. In my own dep ment the theatre sister is a man, and half of the cli nursing staff are males ; and we find that female nu work contentedly with a male "ward sister."

Finally, it may be noted that, while increasing us certainly being made of the male tutor, there are some with the diploma of nursing who have not fo suitable employment. WILLIAM ITTER, S.R.N

Department of Urology, General Hospital,
Newcastle-upon-Tyne.

PROPHYLACTIC PENICILLIN

SIR,—The extension of the use of penicillin to prophylactic field is an obvious one, and it is be widely and increasingly so used in surgery at the pres time. I would, however, like to comment on two po raised by Mr. R. Wood Power in your issue of July

Firstly, his statement that postoperative thromb is caused by infection is not in accord with the wei of present-day evidence or opinion. But apart f theoretical considerations I have had a case of postoperative pulmonary embolism proved by p mortem in a patient whose infection had been comple cleared up by penicillin. It was a case of a carbu which resolved as a result of the giving of 1,600, units of penicillin. A granulating area was left wh was bacteriologically sterile. and some days after area had become sterile a skin-grafting operation performed. The patient died suddenly thirty-six ho after operation from pulmonary embolism. It co of course, be argued that the thrombus developed be the infection was cleared up. But a case such as t added to theoretical considerations, shows that strong positive evidence will have to be brought forw before penicillin can be regarded as a prophylactic aga thrombosis and embolism.

The second point I would like to comment on is use of penicillin in the prophylaxis of postoperat chest complications. I have had two patients ten days after operation developed chest complicati in spite of earlier prophylactic courses of 500,000

,000 units of penicillin. In both cases the inflamma- r trouble was at the bases of the lungs, and clinically ı radiologically seemed to be secondary to collapse. was thought that the collapse may have developed r operation but that immediate inflammatory nomena were prevented by the penicillin.

Vhile not detracting in any way from the extreme ue of penicillin in the prevention of infective pul- nary complications after operation, these cases do phasise that the other factors, chiefly of a mechanical ure, that are concerned in these complications must be combated.

ondon, W.1. DAVID H. PATEY.

SUPPLY AND DEMAND

SIR,—Your annotation under this heading on June 29 most revealing.

During the war, in correspondence in the medical and press, attention was frequently drawn to the civilian actitioner carrying on under great difficulties, and sing only for assistance, and the chance of a "rest" the Forces. To those of us enjoying this "rest" from ngenial work and the presence of our families, this cture always seemed to be a trifle overpainted: We cepted it, but with reservations.

How justified were these reservations is now fully parent. The only body that is displaying any eagerness our assistance is the Army, which has deferred our lease as "operationally vital" until relieved by doctors sh from the hardships of civilian life.

R.M.O., M.E.F.

AID TO DEFÆCATION

SIR,—Some years ago when recovering from an attack lumbar fibrositis I found myself with a difficulty in fæcation owing to any effort at straining being painful. hile at stool I began to rub my lower back to relieve e stiffness, mainly along the line of the lumbar muscles the left side down to the middle of the buttock, and ted after rubbing for a minute or two that the rectum nptied itself easily and with comfort. This appeared obably to be due to reflex stimulation acting through e posterior branches of the spinal nerves. I have ied the effect many times since whenever there was a ndency to constipation, without the use of any laxa- es, and have found it almost invariably successful. hether it acts by stimulating the rectal musculature contract, or whether it relaxes the pelvic sphincter d allows the passage of fæces into the rectum and eir evacuation as a consequence, I have been unable to etermine. No doubt the sceptic will say that the real planation is that more time is allowed for natural nctions to come into play through the time taken in assaging the back, but that is not the case.

Possibly others may find the experiment worth trying. he effect is perceived a minute or two after the massage, hich need not be carried on for more than a minute so. Perhaps it might be described as *vis a tergo* in ntrast with the frontal attack of the usual laxatives.

C. W. B.

NFECTIOUS DISEASE IN ENGLAND AND WALES

WEEK ENDED AUG. 3

Notifications.—Smallpox, 0; scarlet fever, 940; hooping-cough, 2092; diphtheria, 246; paratyphoid, yphoid, 60 (54 in Cardiganshire); measles (excluding ella), 3540; pneumonia (primary or influenzal), 356; erebrospinal fever, 44; poliomyelitis, 23; polio-ence- halitis, 1; encephalitis lethargica, 1; dysentery, 59; uerperal pyrexia, 146; ophthalmia neonatorum, 72. o case of cholera, plague, or typhus was notified during he week.

The number of service and civilian sick in the Infectious Hospitals the London County Council on July 31 was 908. During the revious week the following cases were admitted: scarlet fever, 54; iphtheria, 25; measles, 59, whooping-cough, 32.

Deaths.—In 126 great towns there were no deaths from nteric fever or scarlet fever, 1 (0) from measles, 7 (0) rom whooping-cough, 1 (0) from diphtheria, 36 (6) from iarrhœa and enteritis under two years, and 4 (1) from nfluenza. The figures in parentheses are those for ondon itself.

The number of stillbirths notified during the week was 05 (corresponding to a rate of 31 per thousand total irths), including 37 in London.

Public Health

Typhoid at Aberystwyth

UP to Aug. 12 105 patients had been admitted to hospitals in Wales, and less than a dozen others, suspected of having been infected at Aberystwyth, were in hospitals in England.

Inquiries lead to the conclusion that in the large majority of the patients infection occurred on July 11. Four-fifths of them reside in the borough and rural district of Aberystwyth, and it appears that the most heavily infected portions of ice-cream were consumed by local inhabitants attending church excursions and a youth rally and were not available on a large scale to the ordinary holiday-makers.

The number of cases ascertained from day to day is now beginning to fall. The infection is of only moderate severity, but more deaths are expected.

The suspected carrier is a urinary excretor. Up to the present *Bact. typhosum* has not been found in his stools after four examinations. The organism recovered from his urine belongs to Vi-bacteriophage type C. Organisms of the same type have been recovered from several of the patients.

Poliomyelitis near London

The occurrence of cases of infantile paralysis in three London suburbs has attracted the attention of the daily press. The position is not unusual and the incidence not untoward. Notifications in England and Wales during the six weeks ending Aug. 3 were 8, 9, 12, 10, 18, and 23. In the corresponding weeks of the previous year they numbered 8, 15, 12, 16, 22, and 21, and the upward trends express the usual seasonal rise.

Pre-existing foci were at Barnet and Potters Bar, but during the past week single cases have been diagnosed at Malden and Coombe borough, Sutton and Cheam borough, and Merton and Morden urban district.

Obituary

GEORGE RONALD PYM ALDRED-BROWN

M.A., D.M. OXFD

Dr. G. R. P. Aldred-Brown, consulting physician to the Royal National Hospital for Rheumatic Diseases, died at his home in Bath on July 26. Seven years ago a serious illness had forced him to give up some of his work, but his interest in the hospital was unabated, and he had lately taken a leading part in the development of its occupational therapy department. For some months he had not been well, and last year he retired from the active staff of the Royal National, where for 9 of his 15 years' service he had been senior physician.

Born in 1896, the son of the late Richard Aldred-Brown, controller-general of education in the Egyptian civil service, he was educated at Harrow and Oxford, where he entered Keble College with a natural science scholarship. He broke off his studies to serve, during the 1914–18 war, in the Royal Field Artillery, reaching the rank of captain, and on his return in 1918 he completed his medical course at the London Hospital, graduating B.M. in 1924. Before settling in Bath he held the appointments of pathologist and bacteriologist at the Dorset County Hospital, and his published work included papers on the blood sedimentation-rate and plasma proteins. In 1936 he also published in our columns an article on radiography of the hand in chronic rheumatic diseases—describing the careful investigation of 154 consecutive cases. Last year his growing interest in reablement was responsible for a paper on spa treatment and the injured workman in the *British Journal of Physical Medicine*. A member of the International Society of Medical Hydrology, he was for some years treasurer of the British section. His friends at the Bath Club will remember his expertness at billiards, and he was also keen on golf and lawn-tennis.

Dr. Aldred-Brown married Miss Doreen Crowe in 1925, and she survives him with a daughter, who is at Bristol University.

Notes and News

FOR THOSE IN DIFFICULTIES

In its 26th year the Professional Classes Aid Council report as usual much timely help to professional men and women, or their dependants, who have fallen on hard times. Some, being elderly, are no longer able to work for themselves; others are young and need help to complete their education. Some £3700 has been spent on school fees and outfits for children, and more than £1500 on help to 31 women and 16 men students, of whom 11 were medical students. Many people have had temporary help in time of sickness. The total income of the council for the year came to £14,052, of which nearly £3000 was derived from investments. Happily the year ended with £1658 in hand instead of the deficit of recent years. To maintain their work at the present standard, however, the council will need generous support in the coming year. Those wishing to help should write to the secretary, 20, Campden Hill Square, London, W.8.

University of Cambridge

Mr. *G. D. Greville*, D.SC., has been appointed lecturer in biochemistry.

University of London

Mr. W. C. W. Nixon, F.R.C.O.G., has been appointed to the university chair of obstetrics and gynæcology tenable at University College Hospital medical school, from Oct. 1. For the past two years he has held the chair of obstetrics in the University of Istanbul.

Dr. Ronald Hare has been appointed to the university chair of bacteriology tenable at St. Thomas's Hospital medical school, from Oct. 1.

The title of professor of physiology has been conferred on Mr. W. R. Spurrell, F.R.C.S., in respect of his post at Guy's Hospital medical school.

The title of reader in physiology has been conferred on Mr. L. E. Bayliss, PH.D., in respect of his post at University College; and the title of reader in pathology on Dr. S. J. De Navasquez, in respect of his post at Guy's Hospital medical school.

University of Sheffield

Prof. C. P. Beattie has been appointed to the chair of bacteriology from Oct. 1, in succession to Prof. Wilson Smith, who has left the university to occupy the chair of bacteriology at University College Hospital medical school.

Professor Beattie was educated at Fettes College and the University of Edinburgh, where he graduated M.A. in 1926 and M.B. in 1928. He held an appointment as house-surgeon at the Royal Infirmary and was president of the Royal Medical Society, Edinburgh. In 1930 he obtained the D.P.H. After bacteriological experience in the hospitals and University of Edinburgh, he went, with a Rockefeller fellowship, to the United States and to France, returning to Edinburgh in 1933 as a lecturer in bacteriology. In 1937 he left this country to become professor of bacteriology in the Royal Faculty of Medicine, Iraq; in Bagdad he started the government bacteriology laboratory, which is the bacteriological centre for the whole of Iraq, charged with the preparation of protective vaccines and sera as well as the conduct of bacteriological examinations. Among other duties he set up a quarantine laboratory for the examination of pilgrims returning from Mecca. His researches have covered a wide field, and he has taken a special interest in undulant fever.

University of Durham

Mr. John Boyes, L.R.C.P.E., L.D.S., has been appointed *Nuffield professor of oral medicine.*

North Persian Forces Memorial

The North Persian Forces memorial medal will be awarded again next year, after a lapse of nine years.

This memorial was founded in 1923 by officers of the Royal Army Medical Corps and Indian Medical Service who served with the *North Persian Forces during the war of 1914–18. It is a silver medal* and is awarded annually for the best paper by a single author on tropical medicine or tropical hygiene published during the twelve months ending Dec. 31 by any medical officer of under 12 years' service in the Royal Navy, Royal Army Medical Corps, Royal Air Force, Indian Medical Service, or Colonial Medical Service. Only officers on a regular or short-service engagement are eligible for the award.

A Gift from Sweden

In recognition of medical attendance to Swedes during the war, Sweden recently presented some X-ray equipment to the National Hospital, Queen Square, London. It includes a special Swedish invention in this field—namely, a precision apparatus for cranial radiography, constructed by Prof. Erik Lysholm, of the Serafimer Hospital, in Stockholm, and built by the firm of G. Schönander.

Central Council for Health Education

Lord Woolton has been re-elected president of the council, Sir Allen Daley and Dr. Charles Hill vice-presidents, and Mr. E. G. Savage treasurer. Mr. Henry Lesser, LL.B., has been elected chairman of the council, and Dr. E. K. Macdonald vice-chairman.

Return to Practice

The Central Medical War Committee announces that the following have resumed civilian practice:

Mr. T. KEITH LYLE, F.R.C.S., 42, Charles Street, Berkeley Square, W.1.
Mr. G. C. SAWYER, M.S., F.R.C.S., 6, St. John's Road, Leicester
Dr. J. D. SPILLANE, 110, Cathedral Road, Cardiff.

Medical Diary

AUG. 18 TO 24

Thursday, 22nd

EDINBURGH POSTGRADUATE LECTURES

4.30 P.M. (Royal Infirmary.) Dr. R. M. Murray-Lyon: Ætiology and Diagnosis of Amœbiasis.

Appointments

BICKFORD, R. G., M.B. Camb., M.R.C.P.: research in neurology, Mayo Clinic, Rochester, U.S.A.

BINNING, REX, M.B. Camb., M.R.C.S., D.A.: anæsthetist, Royal Sussex County Hospital, Brighton.

BUCHANAN, D. S., M.B. Durh.: county M.O.H. and school M.O., Huntingdon.

FOSTER, F. G., M.D. Edin.: M.O.H., Birkenhead.

FRESHMAN, EDGAR, M.B. Manc., F.R.C.S.: consulting urologist, Ramsgate General Hospital.

GOODWIN, J. F., M.D. Lond., M.R.C.P.: first asst., medical unit, Royal Infirmary, Sheffield.

HART, F. D., M.D. Edin., M.R.C.P.: physician, Royal Waterloo Hospital, London.

MACPHERSON, IAN, M.D. Leeds, M.R.C.P.: asst. physician, General Infirmary, Leeds.

MEIR, M., M.B. Birm.: asst. surgeon, District Infirmary, Ashton-under-Lyne.

MILLIS, G. C., M.C., M.D. Camb., M.R.C.P.: physician, Royal Waterloo Hospital, London.

MOFFATT, P. McG., M.D. Lond., M.R.C.P., F.R.C.S., D.O.M.S.: consultant ophthalmic surgeon, central medical staff, L.C.C.

MOORE, THOMAS, M.D., M.S. Durh., F.R.C.S.: asst. surgeon, District Infirmary, Ashton-under-Lyne.

RICHMOND, J. H., M.B. Camb.: examining factory surgeon, Wolverhampton no. 1 district.

SEYMOUR-JONES, J. A., M.B. Camb., F.R.C.S., D.L.O.: registrar, Portsmouth and Southern Counties Eye and Ear Hospital.

SMAILES, T. W., M.B. Camb.: examining factory surgeon, Hor Yorks.

SMYTHE, P. M., M.B. Camb.: first asst. and registrar, children's dept., London Hospital.

STEWART, A. B., M.D. St. And., D.P.H.: M.O.H., Paddington (subject to approval of Ministry of Health).

THOMPSON, SYDNEY, M.D. Durh.: dermatological specialist medical referee for county-court districts of Alnwick, Berwick-on-Tweed, Consett, Gateshead, Hexham, Morpeth and Blyth, Newcastle-on-Tyne, North Shields, South Shields, Seaham and Sunderland (circuit no. 1).

THOMPSON, VERNON, M.B. Lond., F.R.C.S.: asst. surgeon, thoracic dept., London Hospital.

TREBLE, H. A., B.M. Oxfd, M.R.C.P.: consulting dermatologist, Ramsgate General Hospital.

WALTON, W. S., M.D. Durh.: M.O.H., Newcastle-on-Tyne.

Births, Marriages, and Deaths

BIRTHS

COLWILL.—On August 4, at Edgware, the wife of Dr. C. K. Colwill—a daughter.

DAYNES.—On August 4, in London, the wife of Dr. Guy Daynes—a son.

EDNEY.—On August 6, the wife of Dr. Roy Edney, of Ashford, Middlesex—a son.

GARWOOD.—On August 4, at Hove, Dr. Dorothea Garwood (Leslie-Smith), wife of Lieut.-Colonel J. C. Garwood, D.S.O., R.E.—a daughter.

RUTHERFORD.—On August 4, at Brighton, the wife of Dr. Raymond Rutherford—a son.

THOMSON.—On August 4, the wife of Dr. J. L. S. Thomson, of Winchmore Hill, N.21—a daughter.

TOMLINSON.—On August 4, the wife of Dr. A. J. H. Tomlinson, of Howitt Road, N.W.3—a daughter.

WILLIAMS.—On August 7, at Swansea, the wife of Mr. Bernard L. Williams, F.R.C.S.—a son.

MARRIAGES

EASTON—LATHAM.—On July 29, in London, Alfred Leonard Tytherleigh Easton, M.R.C.S., to Josephine Mary Latham.

REID—PEDLER.—On July 25, in London, Douglas Andrew Campbell Reid, M.B., M.R.C.S., to Margaret Joyce Pedler.

DEATHS

SLATER.—On July 30, at Godalming, William Arnison Slater, M.R.C.S.

THORNE THORNE.—On August 5, Vernon Thorne Thorne, M.B. Camb., D.T.M. & H., Colonial Medical Service, Nigeria, aged 41.

SERIOUS PSYCHIATRIC DISABILITY AMONG BRITISH OFFICERS IN INDIA

SPECIALISTS IN PSYCHIATRY

I. Analysis of Clinical Material

A STUDY has been made of a group of 150 British fficers with psychiatric illness necessitating their ischarge from the Army or evacuation to the United Kingdom. The hospital in Western India at which his work was done took all such cases from all over ndia and SEAC. No selection has been made except o omit a few cases with inadequate clinical records..

The numbers seemed large enough to warrant an nvestigation of whether the factors involved could be modified to save the wastage of officers, and whether nformation could be obtained which would be of value o selection boards. This investigation can scarcely e regarded as a follow-up of the previous work of he selection boards, since only a few of the officers n this group had passed through the present type f War Office or G.H.Q. selection board. All were dmitted during 1944.

INVESTIGATION

To collect information, a proforma was designed as ollows:

Name ....
Unit ....
Age ....
Total service ....
Indian service ....
Commissioned service ......
Selection board ....
Diagnosis ....
Progress ....
Disposal ....
Previous personality ......
Family history ....

Predisposing factors
(*a*) Action ....
(*b*) Frustration ....
(*c*) Domestic ....
(*d*) Physical ....
(*e*) Inadequacy ....

Precipitating factors:
(*a*) Action ....
(*b*) Frustration ....
(*c*) Domestic ....
(*d*) Physical ....
(*e*) Inadequacy ....

An attempt was made to assess the importance in each case of the following factors:

Previous Personality.—These were considered as (*a*) major defects which had interfered with the patient's work or taken him under treatment: and (*b*) minor defects, such as solitariness, oversensitiveness, and ineffectiveness, which would have been obvious to the skilled observer but might not have (and in some cases had not) prevented their owner from being passed by a selection board.

Family History.—This was investigated from the point of view of (*a*) a home broken by separation, divorce, or death of the parents; and (*b*) a definite history of psychological illness in parent or sibling.

Predisposing factors were those which had been in operation for some three months at least before breakdown.

Precipitating factors were those which occurred just before the onset of the symptoms.

Both predisposing and precipitating factors were split into five groups: (1) enemy action; (2) frustration; (3) domestic; (4) physical; and (5) inadequacy for job.

FINDINGS

The findings have been analysed in tables I–V. Table I shows the incidence of the various disorders n the different arms of the Service, separated into orward and base areas. The following points are shown more easily in separate tables.

(1) The forward-area cases of all types amount to only 20% of the total, whereas the forward-area psychotics comprise 30·4% of all psychotics (table II).

(2) The proportion of forward-area to base-area cases is considerably greater in the Service Corps and infantry than the average, and far higher than in sappers and doctors (table III).

(3) The proportion of schizophrenia to anxiety is higher in infantry officers than in other arms (table IV).

(4) The relative distribution of all officers in the various arms of the Service in India and SEAC, as shown in table I, is only approximate. But it is permissible to note that these 150 cases included 18 doctors (16 from base areas) and 21 sappers (19 from base areas).

(5) The incidence in age- and service-groups would again be liable to mislead, if shown without the distribution of all officers. But it was observed that there was a group of men who broke down within a year of disembarkation, especially within the second six months of that year (31 cases out of the 150). Also that the highest incidence of breakdown was in officers with over 4 years' total service (95 cases); the next highest peak was between 2½ and 3 years' total service (14 cases).

Table V shows the relative importance of factors other than age- and service-groups in the various syndromes.

II. Discussion (R. F. TREDGOLD)

Owing to the fact that the four of us have been scattered, a full interchange of views on the clinical work reported above has not been easy and has been more by writing than by speech. While, therefore, I have incorporated in the following discussion numerous suggestions made by one or the other of my colleagues, and am most grateful for these, the final conclusions must be regarded as my own responsibility.

TYPES OF CASES

The figures are too small to be of much significance, but anxiety states comprised 42·6% of all cases. The association of alcoholism in 6 cases aggravated the condition by producing further inadequacy and irritability, and sometimes criminal irresponsibility. Depression provided only 5·3%, being equalled by paranoid states and outnumbered by manias and hypomanias together.

It was noted by Craigie (1944), in his review of two years' psychiatry in the Middle East, that mania and depression there occurred in approximately the same proportions. This is in contrast, in my experience at least, to conditions in England in 1941, where depression was considerably commoner than mania. The proportion of the two combined compared to schizophrenia was in India approximately 2 : 3 and in Craigie's cases approximately 1 : 3, while in a military mental hospital in 1941 in U.K. it was approximately 1 : 1. This change is undoubtedly partly explained by the fact that the term "depression" is now used more strictly than in U.K., and cases previously labelled "depressive states" would fall into the new nomenclature's "anxiety state." Apart from this, however, there appears to be a real increase in India of manic states, of which the precise cause is difficult to ascertain. Clinically, the cases which were generally slow in onset were slow in progress. Elation was less marked than overactivity, and persecutory ideas were common, being usually, and perhaps not unnaturally, referred to the restrictions necessarily imposed on the patient's military career. It is a possible field for speculation whether an increase of mania is a response to a prolonged sense of urgency engendered by total war.

Schizophrenic states formed nearly 20% and tended to run the course associated with this syndrome in war-time. They were, moreover, associated in many cases with exogenous factors (see below).

INCIDENCE AT THE BASE

The number of breakdowns in base areas is much greater than in forward areas. There are two possible

TABLE I—INCIDENCE OF DISORDERS IN THE GROUP ACCORDING TO ARMS OF THE SERVICE

Diagnosis	Total	Infantry		Engineers		Medical		Artillery		Service		E.M.E.		Ordnance		Armoured		Others

Percentage distribution: Psychiatric cases	100	13·3	7·3	12·7	1·3	10·7	1·3	*8·7*	*2·0*	*4·0*	*2·7*	*6·0*	*1·3*	*6·7*	*0·7*	*2·7*	*0·7*	*15·3*	*2*
Total officers (approximate estimate) ..	100	8·0	6·0	7·0	6·0	9·0	4·0	2·0	6 0	4·0	4·0	2·0	1·0	4·0	1·0	1·0	3·0	21·0	12

The percentage distribution of all British officers in the various arms, in base or forward areas, for the period under review, is unfortunate not available in exact detail but appears to be of the above order.

explanations for this: (1) that in a base area there is a higher proportion of potentially unstable officers; and (2) that the stress in the base areas is greater.

The first explanation would be supported by the observation that the cases here included some who had been given their base jobs because they had been found inefficient elsewhere; in fact, they were throw-outs sent, often in a lower rank, to do what was regarded as a softer job. Inquiry showed that they had never been anything but a menace to an efficient office.

The second explanation appears unlikely. In fact, the reverse is the official opinion of the Directorate of Selection of Personnel (1944): "The staff officer's dealing with persons is . . . carried out under far less emotionally difficult conditions." This, however, is in my opinion open to question. It is true that the infantry officer may at times be exposed to physical and mental strain of a kind and intensity never experienced by his colleague at base headquarters; but this is for very limited periods in between which he is probably physically healthier, and (which is more important) more satisfied. He can, moreover, give vent to his aggressive impulses, and he obtains satisfaction from the crumbs of glory thrown to him by the daily press and from occasional decorations. It is easier for him to feel one of a team; his results and objectives are nearer.

TABLE II—INCIDENCE OF DISORDERS IN FORWARD AND BASE AREAS

Diagnosis	Forward	Base	Total
Anxiety, and anxiety with alcohol	11	53	64
Hysteria	1	11	12
Post-traumatic	..	3	3
Toxic	..	4	4
Psychopathic personality ..	1	10	11
Schizophrenia	10	19	29
Paranoid state	2	6	8
Cyclothymia, hypomania, and mania	4	7	11
Depression	1	7	8
Total	30	120	150

The staff officer, on the other hand, has little or n physical exercise, long office hours, and less hope obtaining promotion by death of his seniors. Thoug the typewriter may be mightier than the machine-gu he seldom has the satisfaction of using the keys himse as an outlet, and any anger or irritation he feels is mo likely to be vented on other departments than on th enemy. In these circumstances it is no wonder th acid letters, childish squabbles over unimportant detail and abuse of rank are known. Once they arise, the aggravate the condition, and there can be few formation where *no-one has thought:* "*We could get on* with th war if only they would let us" ("they" being the ne higher formation). Conversely, the higher formation i quick to sense affronts to its own dignity or infringemen of its rights by the lower, and "So-and-so's private army division, or area" is a term symptomatic of this feeling

McCurdy (1943) has analysed very clearly the reason for the frustration felt by an officer, especially junio with technical competence who ends by "cursing re *tape, cursing his superiors, cursing the stupidity* of th official mind. But there may have been no obstructiveness, but everywhere a desire to do one's best." Balchin's picture in *The Small Back Room* expresses such feelings most graphically.

Other evidence of this tension is the sense of "being out of it," which nearly all base officers display. Termed by some "non-combatant guilt," this may be underlying shame at not being exposed to personal danger when others are, particularly if these are close friends or likely, after the war, to be close neighbours. The projection of this feeling is the cause of the emotion engendered in base areas over anyone suspected of "shirking."

It must, therefore, be seriously considered whether there *is not as much psychological stress to* be encountered by officers in base areas as by those in moderately close contact with the enemy. The figures of incidence in this *study seem to support this suggestion.*

In any case, there can be no doubt that the diminution of the stress described in base areas is a problem of high practical importance. On the efficient *functioning* of staff work depends, obviously, the success of the battle. It is as dangerous to clutter up staffs with unsuitable officers as it is to put potential psychiatric casualties in tanks. The result may be less striking and less easy to assess, but the loss of efficiency to the whole Army can be assured.

The first step to a solution is a realisation of its complications; for example, it is much easier to accept an over-severe letter, if it is viewed rather as a symptom of frustration than as one of a permanent attitude of mind (bloody-mindedness); and the recipient is more likely to indulge in satisfactory action than in a counter-attack. (In the same way it is easier for a doctor to accept the rudeness of a patient, which he knows to be symptomatic of underlying psychological trouble, than the plain speaking of an apparently reasonable friend. This sometimes produces the paradox that the more reasonable the friend, and the advice, the more resentment is felt and the less is the advice followed.)

This realisation can undoubtedly be helped by visits; the officer who has been previously but an illegible signature or an indistinct voice on the telephone surprisingly becomes a human being.

It would also be valuable to see that the public (and so the staff officer too) are kept informed of the need for, and the importance of, staff work in continuing the war.

Physical exercise, regular leave, or at least a change of scene, and some time off once a week, are essential. Such measures may be scorned by the strongest of us but will influence the weaker, who are here our problem. It is the lack of all the above which damages the individual's sense of proportion and sense of humour, which should be firm sheet anchors of his stability.

TABLE III—FORWARD- AND BASE-AREA CASES IN SEVERAL ARMS

Area	Service Corps	Infantry	Engineers	Medical	Others
Forward ..	4	11	2	2	11
Base ..	6	20	19	16	59

If efficient planning is essential, those who provide it should be honoured as much as the combatant, and every effort should be made to bridge the gulf which splits the Army. In parentheses, it is questionable whether arm-bands, which accentuate the difference between staff and combatant, serve a useful purpose.

SPECIALISTS

(1) The proportion among the R.A.M.C. and I.A.M.C. is very disturbing. It has been noted elsewhere, and Reider (1944) produced an interesting explanation. He suggested that doctors were largely attracted by the feeling that they had power of life and death over their fellows or by a narcissistic satisfaction of being closer to God. He considered that this was impossible in the less personal framework of the Army, and that the M.O. suffered from its loss.

Even if this theory were accepted, it would not seem a full explanation; for opportunities for "narcissistic satisfaction" are by no means absent from the ordinary M.O. and to some extent are encouraged by his brother officers in the mess. It seems more probable that other factors have more weight: lack of physical fitness, and so lack of resistance to intercurrent infection; some, but incomplete, knowledge of the possibilities of tropical disease; and lack of personal morale, owing either to inability to vent one's aggressive tendencies as well as one's fellow, or to the proximity in base hospitals of many patients whose morale is lower than that of men in the front line.

TABLE IV—INCIDENCE OF VARIOUS DISORDERS IN SEVERAL ARMS

Diagnosis	Infantry	Engineers	Medical
Anxiety states	12	9	9
Schizophrenia	10	3	3
Cyclothymia, hypomania, and mania..	3	2	4
Other diagnoses	6	7	2
Total	31	21	18

Alternatively, it has been suggested that the doctor's basic ideology is brought into sharp conflict with the needs of the military machine. This, however, is scarcely such a conflict (for most doctor's efforts are still directed to healing, directly or indirectly) as that experienced by the average citizen called on personally to learn to kill.

(2) The number of sappers also calls for inquiry. These, again, were predominantly from base areas rather than field units. The patients appeared to have done a comparable job perfectly satisfactorily in England but to have soon failed in India. They were asked why

TABLE V—RELATIVE IMPORTANCE OF FACTORS IN VARIOUS SYNDROMES

Diagnosis	Total	Previous personality defects		Family history		Predisposing factors					Precipitating factors						
		Gross	Minor	Bad environment	Bad heredity	Action	Frustration	Domestic	Physical	Inadequacy	Nil	Several	Action	Frustration	Domestic	Physical	Inadequacy
Anxiety	58	6	20	9	5	10	3	10	11	18	..	8	6	9	18	12	21

they thought this was. The following extracts are an answer:

> ". . . Apart from the usual troubles of language difficulties, dumb insolence, very often assumed, maybe, physical differences of race, methods of execution of work, and the age-old lacking of drive and will-chase to get a job done. Those things one can expect but cannot realise their depth until experienced. There is one great factor, which will in time bring *many* Works Service personnel to you, or very nearly, and certainly demoralise many previously industrious and keen men—that is, graft."
>
> "I have fought hard against becoming 'bolshy'—when surrounded by discontented men—but having had much time to think, I find that anyone coming to India even 100% fit, not war-weary or overworked in the past, any reasonably conscientious person who is anxious to do his job, get on and do as much as he can, knowing that a large number are really fighting; that person is going to find himself against a brick wall."
>
> "I was recommended for my majority within nine months of *joining the army—so feel I'm adaptable to changed* conditions. When engineers are sent out in the 35–40 age, with quite a lot of building experience, let a psychiatrist watch their postings, or (better still) give them an emotional test as part of their home medical for tropical service."

By some these comments will be regarded as the outpouring of an unstable man, anxious to justify his failure. It is my opinion, on the contrary, that they should merit very careful consideration. They are by no means exceptional and have been confirmed by men who had no psychiatric disorder.

Generally speaking, specialist corps appeared also to feel frustration more than did combatant officers, partly because they were more often kept hanging about without a job than were infantry officers, partly because it galled them more that their expert knowledge was being wasted. It was not rare for officers to leave England under the impression (probably accurate) that there was a great demand for them in India, but to arrive at a unit where no-one seemed either to expect or to welcome their coming. Vague promises of promotion implied in England were obviously only likely to be fulfilled after a considerable delay—if at all.

AGE- AND SERVICE-GROUPS

Unfortunately the relative proportions of various age-groups among British officers throughout the Indian theatre of war cannot be assessed, but it may be noted that the proportion of psychoneuroses, mostly anxiety states, in men of less than 30 and more than 40 years of age was very considerably higher than in the age-group 30–40. The psychotics, most of whom were schizophrenics, again tended to occur before 30 years of age.

The relative scarcity of serious psychiatric conditions among those of less than $2^{1}/_{2}$ years' total service is obvious, as is the gradually increasing burden of longer service. Nearly 60% had been serving at least since Dunkirk, where they had no doubt acquired some predisposition. Many had had commissions all the time or been passed early in 1942 by the older form of board.

The length of service overseas is of interest in that the heaviest incidence occurs in those with less than a year's service, and after this is spread out more or less evenly from $1^{1}/_{2}$ to 3 years.

It may further be noted that among those who broke in less than a year the preponderance was of young schizophrenics and psychoneurotics.

The fact that over 30% of the patients broke down so severely within twelve months of arriving in India is a disturbing reflection. Few of these men had been exposed to enemy action or had physical ailments. The important factor, as will be later discussed, was inadequacy in their unit. This is probably explicable on one of several grounds:

(1) That men were deliberately sent out to India who were not wanted in U.K. when preparations were in progress *for the Second Front.*

(2) That lack of coördination in posting led at times, as discussed above, to leaving a man, busy enough at home, in idleness here.

(3) That men previously satisfactory and adequate in U.K. were unable to be so in India, either because of separation from home, physical weakness, complete lack of preparation for local difficulties, or several factors combined.

Many officers arrived with preconceived ideas about India which did them no good. Either they had heard tales of "the brightest jewel in the crown of the Empire" and were ill prepared for the need for quarrying away the dirt to get at the jewel, or their natural mild home-sickness was allowed to become exaggerated on the boat and projected on the various alleged drawbacks of India: poverty, squalor, and corruption which those of previous experience described luridly. There were further, the mild attacks of diarrhœa and excessive sweating due to climatic conditions, to all of which they had to adapt themselves.

Again, commissioned service was commonly less than a year, or between $2^{1}/_{2}$–3 years. The explanation for this is obscure, but it is probable that some were men who had been commissioned in U.K. soon after Dunkirk and, after serving some six months there, had been exposed to moderate but prolonged stress in India.

FAMILY HISTORY

The proportion of broken homes among these cases may be higher than in a normal cross-section of the population, but the figures are scarcely significant. Hereditary factors were noted in over 25% of the psychotics.

Marriage.—The number of married and single men has not been recorded, since the details were not considered full enough to give any reliable evidence. It is felt that such figures would tend to mislead, unless a more profound study of the patients' reaction to marriage than was possible could have been made. The report made by Hastings et al. (1944) on the Eighth U.S. Air Force showed that the young fliers, unencumbered by domestic responsibility, were on the whole the more stable and it suggested tentatively that it might be wise to forbid marriage for one or two years after graduation from flying training. This suggestion takes no account of those, who must have existed, whose stability was increased by marriage and the founding of a family.

PERSONALITY TRAITS

It was noteworthy that as many as 12 had evidence of a previous major breakdown. As might be expected not one of these had passed through a W.O. or G.H.Q. selection board, though they had been selected after an interview by a (non-medical) board. Only 12 of all the 150 officers had seen a W.O. or G.H.Q. selection board.

The number of minor personality changes may be considered in more detail. This question is obviously very closely bound up with the number of such traits which could be found by careful questioning in the total population, on which very different views are held. Close statistical survey is obviously required before we can come to any definite opinion on the matter, and no detailed study will here be made of the number of so-called psychoneurotic traits (nail-biting, &c.). Instead, attention was concentrated on minor defects which had interfered at some stage with their adaptation to army life, and hence their value. Briefly, they were mostly signs of inability to mix or assert oneself. These were present in 39% of the total, mostly in the hysterics, the psychopathic personalities, and the schizophrenics. Moreover, in these they were associated with feelings of inadequacy at work, which had before been generally kept within bounds but recently had increased rapidly.

PREDISPOSING AND PRECIPITATING FACTORS

In all but a very few cases, both predisposing and precipitating factors were evident, but they were of ferent groups which, perhaps, bore some relation to the vious personality.

Enemy Action.—It is perhaps noteworthy that enemy tion did not play a larger part, especially when it is nembered that all British officers being evacuated for ychiatric conditions from India and SEAC within is period would be included within this group.

Also, it was the schizophrenic whose breakdown s precipitated by action. It might be argued that the hizophrenics got as far as the enemy because they peared, to their colleagues, to be perfectly normal d so were not "eliminated," whereas the psychopaths d hysterics were prevented by O.C. or colleagues om running risks. There may be some truth in this, t it would not be on a large scale. One psychoth got as far as the enemy. Although in such cases e might expect a previous loss of initiative, war schizophrenics" are atypical, and it is possible that e explanation is rather that these schizophrenics had mething the others (psychopaths and hysterics) had ot got—initiative and drive—which positive factors ould have outweighed, at least in the eyes of comrades nd commanders, their negative disadvantages—a point hich perhaps has implications regarding the value of ssessing positive qualities as well as negative. Men ith undoubted personality defect can be accepted nd can be of value if (but only if) these defects are ounterbalanced by the possession of some initiative, genuity, intelligence, and courage.

Frustration was an important factor in more cases nd contributed to anxiety, hysteria, and schizohrenic and paranoid states, colouring, as might be xpected, the clinical picture.

Frustration also prevented the recovery of convalescent fficers from the difficulty of obtaining satisfying employnent for them. A vicious circle was again likely, as is asy enough to understand. Officers who were the very ype to need consideration at the start of a new job were ften by their nature least likely to get it. The waits and isappointments on arriving at a new unit, which may ometimes be regarded as inevitable in such a complex nachine as the Army in India, and accepted by most vith resignation, were taken by weaker brethren as an asy target on which to project their separation anxiety, and irritation with their senior officers became almost as ixed in them as intense dislike of India was among those whose target was the Indian scene.

Domestic stress largely led to anxiety and was common nough. Examples of stress were bereavement, worry over illness, financial loss, post-war prospects, and concern over real or suspected infidelity, though this last concern is less common among officers than among other ranks.

The *physical disabilities* were generally severe attacks of amœbic dysentery, malaria, or infective hepatitis. Though I would be the last to propose that any of these conditions are without psychological effect on their own unfortunate victims, the results in the cases quoted were not often due to this; rather they were due to the impression which was allowed to gain strength in the patient's mind (at his first attack and onwards) that he was unusually predisposed to such conditions, or unusually weakened by them, and that he would never be well again till he returned to U.K. In such cases, especially in dysentery, as might be expected, symptoms persisted, and this reinforced his conviction. Treatment, to be of any value, had to be given in the very early stages before this idea became fixed; unfortunately, it often was not. As Menninger (1943) puts it, "the end-result was not a blood-stream infection or a gastrointestinal disease, but a disorder of the whole organism —a disorder of thinking and living."

Inadequacy was common among the anxiety states, he schizophrenics, the hysterics, and the psychopaths. In anxiety states and schizophrenia it was generally a secondary effect, due to the illness and later aggravating it. The hysterics and the psychopaths were naturally inadequate and in no way capable of shouldering normal responsibilities.

PROPOSALS

It can scarcely be denied that the wastage of officers on this scale is serious in its military effects and, possibly, in its medical and social implications. This must be the excuse for discussing such a statistically small number and for venturing to draw conclusions and suggesting proposals to counteract the existing factors.

Breakdown soon after arrival is dangerously common. It is due partly to bad selection, completely inadequate officers having been sent. Some were literally worse than nobody, for they were a dead weight on their units —in particular their C.O.s—and on the medical services. If there were no-one better to send, it would have been better to send no-one.

Selection should obviously be carried out by the machinery of the Directorate of Selection of Personnel. The selectors should beware of young immature men who may not be able to adapt to separation, especially if there are any suggestions of hysterical reactions or emotional abnormality.

Breakdown is also due to a combination of physical ill health, homesickness, and frustration, all of which reinforce each other directly (and indirectly, in that they prevent improvement). This could to some extent be prevented by insisting that mental adaptation to various difficulties must be made before disembarkation. For this purpose a clear statement of what is to be expected, and what will have to be endured physically and mentally, would be beneficial.

The breakdown of many officers after four years' service may well be explained on grounds of fatigue or "war-weariness," which was perhaps inevitable. There is no doubt that if breakdown develops in the few loss of efficiency will develop in the many, and it was wise to base demobilisation on age plus length of service. It was, on the whole, in the officers with long service that domestic stress and physical ill health had most effect. It is probably fair to conclude that it would be improved if long periods of leave at home could be granted after considerably shorter service.

A closer understanding by those in base areas of the reasons for the stresses they undergo might minimise their effect and at the same time promote closer sympathy and coöperation between formation headquarters.

SUMMARY

A study has been made of 150 British officers evacuated on psychiatric grounds from India and SEAC, and an attempt to analyse the various factors concerned in each is described.

Tables of this analysis are shown, and comments are made on the relative importance of the different factors.

Proposals are made to diminish the strength of the operative factors and to call for a closer selection of officers for overseas service.

Our thanks are due to Major-General H. C. D. Rankin, then D.D.M.S. Southern Army, India Command, and to Colonel G. Moulson, then commanding an Indian base general hospital, for permission to publish these findings and for much helpful criticism.

VITAMIN A AND SKIN DISEASE

Z. A. LEITNER
M.D. Berlin, L.R.C.P.E.
CLINICAL ASSISTANT, ST. MARY'S HOSPITAL, LONDON

T. MOORE
D.Sc. Belf., Ph.D. Camb.
DUNN NUTRITIONAL LABORATORY, UNIVERSITY OF CAMBRIDGE, AND MEDICAL RESEARCH COUNCIL

CLINICAL research on vitamin-A deficiency as a cause of skin abnormalities has developed in several phases. The first phase originated in the observation that skin lesions were often a complicating factor in people with eye lesions, which were later attributed to deficiency of vitamin A. Thus the association of keratomalacia and xerophthalmia with dry scaly skin was noticed by de Gouvêa (1883), Mori (1904), and Bloch (1921). In groups of adult Chinese with keratomalacia, Pillat (1929) and Frazier and Hu (1931) found that the skin was dry and covered with flakes of horny epithelium. They also observed, on the extensor surfaces of the arms and legs, a characteristic eruption of raised papules, which resulted from the blocking of the hair follicles with cornified material. The condition of the skin was much improved by a diet rich in vitamin A. Loewenthal (1933) noted similar lesions in East African prisoners. The papular eruption was present in all cases having xerophthalmia or defective dark vision, and was cured by the administration of cod-liver oil without any other treatment. Nicholls (1938) reported that symmetrical papular eruptions, with dryness and scaliness of the skin, were common among inmates of Ceylonese prisons. The condition was associated with xerophthalmia and keratomalacia, and sometimes with dysentery and neuritis. Nicholls called the skin lesions phrynoderma, a Greek version of the native name of toad-skin.

In this country Goodwin (1934) described a single case with papular eruptions which he considered to be due to vitamin-A deficiency, and which was cured by a suitable diet and cod-liver oil. Youmans and Corlette (1938) had similar experience with 20 cases in America. In infants Helen Mackay (1934) found that the provision of additional vitamin A above that present in the ordinary diet decreased the incidence of sore buttocks, intertrigo, and napkin rash. Lehman and Rapaport (1940) observed follicular papules in association with defective dark-adaptation in American families in receipt of financial relief, and cured both abnormalities by giving massive doses of vitamin A for several months. In India, however, workers in Aykroyd's laboratory found that the severity of eye and skin lesions did not always run parallel, and they raised doubts whether vitamin-A deficiency was the sole cause of phrynoderma (Aykroyd and Rajagopal 1936, Aykroyd and Krishnan 1937, Rao 1937).

Fitzgerald Moore (1940) has emphasised the importance of distinguishing the effects of vitamin-A deficiency from those of pellagra, and Wiltshire (1919) pointed out that in scurvy a condition of follicular hyperkeratosis occurred which was very similar to that of vitamin-A deficiency. Stannus (1945) and Leitner (1945) have also questioned the specificity of vitamin-A deficiency as the cause of phrynoderma and similar conditions, which Stannus considers are identical with keratosis pilaris as seen in this country.

Vitamin A in Common Skin Diseases.—In a second phase of research the problem has been attacked from the opposite direction. Instead of studying skin lesions in subjects believed to be suffering from vitamin-A deficiency, workers have examined the adequacy of the vitamin-A status in subjects with skin disease. The methods of approach adopted by different investigators have included estimations of vitamin A in the blood-serum by chemical methods, the examination of dark-adaptation, and the observation of the clinical effects of dosing with vitamin A.

Marchionini and Patel (1937) found that the serum-vitamin-A level was lowered in eczema and psoriasis but normal in furunculosis. In nearly 300 patients with various skin diseases, Schneider and Widder (1938) reported that the average carotene was 25% below normal and vitamin A 36% below normal. Gross (1941) found that cases of nummular eczema were often cured with large doses of vitamin A, and Cutler (1940) also claimed that the combined administration of vitamins A and D was beneficial in eczema, and even went so far as to suggest vitamins have an anti-allergic action.

In atrophic eczema, besides other allergic conditions, Spector et al. (1943) found a defective absorption of vitamin A, as indicated by an abnormally low increase in the serum after heavy dosing. Similarly, in infants with severe generalised eczema associated with retarded development, lymphadenopathy, and respiratory infections, Sant' Agnese and Larkin (1943) found that the absorption of vitamin A was insufficient.

In spite of some measure of agreement between the above-mentioned workers, Cornbleet et al. (1944) found that in patients with common skin diseases the serum-vitamin-A level was always above the "lower normal limit."

Porter and Godding (1945a) found no abnormality in the dark-adaptation of patients with common skin diseases.

Vitamin A in Rare Skin Diseases.—A third phase of research may be recognised in the recent interest in the significance of secondary or conditioned deficiency of vitamin A in the ætiology of some rare skin diseases, chiefly of hereditary origin.

Darier's disease, in which the essential lesion is a keratosis of the mouth of the follicles, is characterised by firm pin-head-sized confluent papules which soon become crust-covered and later produce vegetating papillomatous growths. The eruptions usually appear on the face and neck and may spread all over the body. Peck et al. (1941, 1943) reported that the serum-vitamin-A level was low. Treatment with massive doses of vitamin A (200,000 I.U. daily) not only increased the serum-vitamin-A level, but also in almost all cases had a favourable clinical effect. They suggested that Darier's disease was due to hereditary or acquired weakness in the absorption of vitamin A, or in the conversion of carotene to vitamin A. In support of this conclusion several other workers (Barwasser 1941, Cannon 1941, Sweitzer 1942, Michelton 1942, Abramovitz 1942) all reported one case each, which usually improved after treatment with vitamin A. The experience of Carleton and Steven (1943), however, was somewhat inconclusive. Dark-adaptation was normal in all cases of Darier's disease at their disposal. The serum-vitamin-A level was low in only one out of four cases, but two improved clinically when given moderately large doses of vitamin A (20,000 I.U.). Pettler (1942) observed no clinical improvement in a case of Darier's disease given massive doses of vitamin A.

Devergie's disease, or pityriasis rubra pilaris, is a chronic exfoliating skin affection in which the papules coalesce to form reddened scaling areas, which spread over parts, or sometimes the entire surface, of the body. The course of the disease is chronic and irregular, with unexpected exacerbations, and there is a tendency for the lesions to become generalised in the form of an exfoliating erythrodermia.

Cures in two patients who were dosed with vitamins A, B, and D were reported by Pettler (1936), and carotene was later found to be effective in one patient (Pettler 1942).

One aged woman was cured by Arquello (1940) with massive doses of vitamin A, but Thomas (1943) obtained no response in an aged man. Brunsting and Sheard (1941) cured defective dark-adaptation in three patients with this disease with daily doses of 150,000 I.U. of vitamin A. The skin was improved in two of their cases, and became stationary in the third. Peck and Chargin (1941) cured one patient of extensive lesions by massive dosing with vitamin A.

The experience of Weiner and Levin (1943) was perplexing; though they successfully treated the skin lesions in five patients by dosing with vitamin A and carotene, they could not before treatment detect any abnormality in the levels of these substances in the blood, nor in dark-adaptation. Cornbleet et al. (1944), however, found that the plasma-vitamin-A level was low in a boy with pityriasis rubra pilaris. In contrast the plasma carotene was high, and they concluded that the problem must be one of incorrect utilisation or transformation of the provitamin rather than of dietary deficiency or defective bsorption.' Porter and Godding (1945b) found in a single atient that dark-adaptation was subnormal and was cured, nd the skin lesions considerably improved, by protracted dosing with vitamin A.

In *ichthyosis*, another rare disease, Rapaport et al. (1942) found that the skin lesions were associated with poor dark-adaptation, and that both abnormalities were improved by giving large doses of vitamin A. In agreement with these findings, Peck, Glick, and Chargin (1943) observed that the plasma-vitamin-A level was low in ichthyosis; but, though the serum-vitamin-A level was increased by dosing, the improvement in the skin was hardly outside the usual seasonal fluctuation.

Glazebrook and Tomaszewski (1944) investigated the vitamin-A status in a man with Hodgkin's disease, with severe injury to the liver and general ichthyosiform atrophy of the skin. There was great deterioration in dark-adaptation, and the serum-vitamin-A level was very low. A further indication of abnormality was found in the excretion of small amounts of vitamin A in the urine, from which it is invariably absent in normal subjects.

Primary and Secondary Deficiency of Vitamin A.—The relation of vitamin-A deficiency to skin disease seems therefore to be complex. It seems clear that the follicular lesions may arise from several causes. Thus they occur in hypovitaminosis C (Wiltshire 1919) and in subjects in whom no dietary deficiency might be expected (Stannus 1945). The differential diagnosis of the various causes of follicular lesions, if always possible, is obviously very difficult. Moreover in patients who are cured with vitamin A, particularly in Darier's disease and pityriasis rubra pilaris, we must not neglect the possibility of the spontaneous remissions which are an occasional feature in these diseases.

TABLE I—PLASMA-CAROTENOIDS AND PLASMA-VITAMIN-A LEVELS IN COMMON SKIN DISEASES

Group	No. of cases	Mean values (I.U. per 100 ml.)	
		Carotene	Vitamin A
Eczemas	26	109	126
Pityriasis rosea	5	119	92
Psoriasis	10	161	117
Seborrhœa	11	144	128
Lupus vulgaris	4	214	84
Lichenifications	13	139	123
Acne vulgaris	4	99	119
Rosacea	8	100	122
Skin infections	11	132	119
Alopecia	5	186	114
Pruritus	3	139	128
Verruca	1	84	101
Urticaria pigmentosa	1	55	78
Erythema nodosum	1	170	127
Lymphogranuloma inguinale	1	106	73
Pityriasis lichenoides chronica	1	104	284
Means for above 105 cases	..	130	120
Keratosis follicularis	6	126	74
Pityriasis rubra pilaris	2	150	97
Ichthyosis	3	105	71
Means for all 116 cases	..	130	116

TABLE II—PLASMA-CAROTENOIDS AND PLASMA-VITAMIN-A LEVELS IN CONTROLS

"Normal"	41	161	118
Accidents	4	141	78
Fractures	12	102	92
Arthritis	18	145	114
Varicose veins	19	110	123
Herniæ	18	133	110
Hæmorrhoids	4	139	117
All controls	116	139	113

Answers are required to at least three distinct questions: (1) Has it been proved conclusively that in tropical or oriental countries dietary deficiency of vitamin A does in practice cause skin disease? If so, are the diseases ascribed to vitamin-A deficiency due solely to this defect? (2) Are common skin diseases in temperate countries caused or aggravated by dietary deficiency of vitamin A? (3) Can the evidence be accepted which suggests that secondary deficiency of vitamin A, resulting from abnormal metabolism, is an important feature in certain rare skin diseases?

There was no opportunity in the present work to study vitamin A in tropical skin diseases. From the examination of vitamin A and carotene in numerous dermatological subjects in this country, however, we have obtained evidence which may be valuable in answering the second and third of the above questions.

EXPERIMENTAL

Material.—The present paper gives the results of chemical estimations of carotenoids and vitamin A in the blood-plasma of 116 subjects treated for various skin diseases either as private patients or as outpatients at St. Mary's Hospital. Most of the specimens were collected between November, 1944, and March, 1945, but 18 specimens were obtained before this period. In subjects with common skin diseases specimens were usually taken on a single occasion only, but in selected cases of Darier's disease or of pityriasis rubra pilaris serial estimations were made, and the effect of massive doses of vitamin A on the level in the blood was examined. To serve as controls, specimens were collected over the same period from healthy subjects, or from patients suffering from accident, fracture, arthritis, varicose veins, hernia, or hæmorrhoids. Cases involving pregnancy, hypertension, or other conditions believed to affect the blood-vitamin-A level were excluded from the control group.

Methods.—The technique differed only in minor refinements from that of Kimble (1939), as modified by Yudkin (1941) and by ourselves.

The plasma (6 ml.) was shaken with alcohol and petrol ether. Carotenoids were estimated in the extract, after suitable clarification, by their natural yellow colour. The extract was then evaporated, and vitamin A estimated by the blue colour produced on treatment with antimony trichloride, an allowance being made for the colour contributed by carotenoids to this reaction. Both yellow and blue colours were measured in a photoelectric absorptiometer provided with suitable filters.

In calibrating this instrument against a specimen of vitamin-A acetate a conversion factor of 1600 between $E^{1\%}_{1\text{ cm.}}$ 328 mμ and I.U. of vitamin A per g. was assumed. The calibration for carotenoids was against the international standard solution of β-carotene, and for convenience results have been expressed as though all the carotenoids of the plasma were β-carotene. Owing to the presence of xanthophyll, α-carotene, &c., the actual "biological value" of the carotenoid fractions was presumably somewhat less than the figures given.

Results.—The mean values for plasma carotenoids and vitamin A in various skin diseases are given in table I. For all types of skin disease combined, the average values were 130 I.U. for carotenoids and 116 I.U. for vitamin A. These figures are almost identical with the corresponding means of 139 and 113 I.U. found for the controls (table II).

In agreement with general experience the individual values for carotenoids and vitamin A varied over a wide range in both the dermatological and control subjects. If, however, we fix arbitrary limits of 0–80 I.U. as indicating low values for either carotenoids or vitamin A, 81–160 I.U. as indicating medium values, and over 161 I.U. as indicating high values, there again appears to be little difference between the two series. The percentages of cases falling within these limits were as follows:

		Percentage of cases		
		Low	*Medium*	*High*
Carotenoids	Skin disease	21	55	24
	Controls	16	54	30
Vitamin A	Skin disease	22	63	15
	Controls	22	65	13

Since secondary deficiency of vitamin A has been reported in Darier's disease, pityriasis rubra pilaris, and ichthyosis, our data for patients with these diseases are summarised in table III. Mean values are given for all the specimens of plasma collected from each subject while still uninfluenced by vitamin-A therapy. Other columns give the lowest recorded values found without vitamin-A therapy, and the highest values found after massive doses of 100,000–240,000 I.U. of vitamin A had been given over prolonged periods.

TABLE III—PLASMA-CAROTENOIDS AND PLASMA-VITAMIN-A LEVELS IN CERTAIN RARE SKIN DISEASES

Our findings indicate that the plasma-vitamin-A level is often, but not invariably, low in these diseases. In comparison with the mean value of 116 I.U. found in the controls, the mean for Darier's disease was 74 I.U., for pityriasis rubra pilaris 97 I.U., and for ichthyosis 71 I.U. For all 11 patients the mean was 77 I.U., as against 113 I.U. for the controls. In only one instance was a mean value obtained which exceeded the mean value for the controls. Eight cases at one time or another gave values which were less than half the average for the controls.

In subjects given massive doses of vitamin A the plasma-vitamin-A level always rose eventually to very high levels, in one instance (case 5) reaching nearly 2000 I.U. In each subject the values after dosing fluctuated considerably. This may have been due in part to difficulty in ensuring that the specimens should be collected at a constant interval of five hours after dosing, which was intended to coincide to the point of maximal absorption of the vitamin into the blood-stream.

In case 7, a boy with severe pityriasis rubra pilaris, the plasma-vitamin-A level did not respond normally to massive doses of vitamin A during the early stages of therapy. Thus after two months' treatment with up to 150,000 I.U. daily of vitamin A the plasma-vitamin-A level was only 82 I.U. In contrast to the experience of Cornbleet et al. (1944), the plasma carotenoids were also consistently low and, during eighteen months' observation, had a mean value of only 71 I.U. In this patient the galactose tolerance, serum-choline esterase, and hippuric-acid tests indicated impairment of liver function, which was probably the cause of the poor response of the plasma-vitamin-A level to dosing.

The fall of the plasma-vitamin-A level after the discontinuance of massive dosing with vitamin A was studied in case 5 with Darier's disease and in one normal subject. In each case there was a rapid decrease during the day after the last dose, which was followed by a slower decline to a constant level slightly above the mean value for the controls. Thus case 5 gave a value of 522 I.U. at five hours after her last dose, 200 I.U. after twenty-four hours, 135 I.U. after three days, and 118 I.U. after three weeks. The control had 1120 I.U. at five hours after dosing, 156 I.U. after thirty hours 131 I.U. after a week, and 126 I.U. after two weeks. Too much importance need not be attached to the difference shown by the two subjects at five hours after dosing, because the rate of change in the plasma-vitamin-A level at this point is obviously very rapid. On several other occasions case 5 gave values of over 1000 I.U.

The clinical course after dosing with vitamin A in Darier's disease and pityriasis rubra pilaris varied in different patients. The vitamin therapy was combined with treatment with Grenz rays, and any improvement for which the vitamin might have been responsible was assessed by the inspection of areas of skin not exposed to the rays. In two young patients with Darier's disease dosing with vitamin A was followed by complete or nearly complete recovery. In other subjects such progress as was observed might well have been due to spontaneous remissions. Case 5, in whom the highest plasma-vitamin-A level was found after dosing, did not show any clinical response to therapy. The two cases of pityriasis rubra pilaris both improved during dosing with vitamin A, but neither was entirely cured. No cases of ichthyosis were treated.

Some of the above-mentioned cases were demonstrated at the Royal Society of Medicine (Leitner 1946, Moore 1946) and all are still under observation.

DISCUSSION

The results of our investigation do not favour the view that vitamin-A deficiency is prominent in common skin diseases in this country. Our failure to detect any difference in vitamin-A status between groups of dermatological and control subjects is in agreement with the recent conclusions of Cornbleet et al. (1944) and of Porter and Godding (1945a) and in contrast with the claims of many earlier workers.

As regards Darier's disease, pityriasis rubra pilaris, and ichthyosis our data give limited support to the conclusion that secondary deficiency of vitamin A may be a significant factor. It must be emphasised that in none of these diseases have we observed vitamin-A values consistently under 40 I.U., which is the level below which there is danger of functional deficiency of vitamin A, as indicated by gross impairment of dark-adaptation (Medical Research Council 1945). We have, however, occasionally obtained values below this level in three cases of Darier's disease. In two other patients the lowest observed values were under 50 I.U., and in three more under 60 I.U. Wide variations were usually found, however, both between patients with the same disease and between successive estimations in the same subject. Thus case 7, with severe pityriasis rubra pilaris, gave low values for the plasma-vitamin-A level. His mother, however, who had the same disease, but in less active form at the time, gave a mean value above the average for the controls. Similarly, case 6, in contrast to the other patients with Darier's disease, never showed a low plasma-vitamin-A level. It may be significant that her lesions were unusually mild. The degree of individual variation may be illustrated by case 4, whose plasma-vitamin-A level varied on different occasions between 7 and 93 I.U. Except in case 7, we found no evidence of any lack of absorption of vitamin A from the intestines, as indicated by its increase in the plasma after the ingestion of massive doses.

Our observation that the plasma-vitamin-A level is often low, but sometimes normal, in the diseases in question may explain the diversity of opinion of previous workers on this point. Factors which might be expected to cause variations between different subjects are the severity of the disease and the degree of injury to the liver. In individual subjects the extent of the skin lesions may often be subject to intermittent exacerbations and remissions, which may depend on factors such as season, diet, and endocrine activity, and may well be accompanied by corresponding changes in the plasma-vitamin-A level.

Finally two points may be emphasised. First, it must not be assumed that, if vitamin-A deficiency is of little importance in this country as a cause of the commoner skin diseases, the same conclusion can necessarily be applied to all other vitamins. The possible significance of vitamin C, for example, remains an open problem. Secondly, it must be understood that, when massive doses of vitamin A are given, of the order of 200,000 I.U., compared with the minimal curative dose of 1250 I.U. (Medical Research Council 1945), the vitamin is temporarily carried in the plasma in amounts greatly in excess of the normal physiological level. This "supercharging," in which the rate of intake of the vitamin outstrips the power of the liver to absorb the excess from the plasma, may well lead to the appearance of the vitamin in tissues from which it is usually absent, or from which it has been excluded by the disease. Massive dosing with vitamin A, therefore, may in some circumstances have therapeutical effects not conferred by mere dietary sufficiency.

SUMMARY

In an examination of plasma-vitamin-A levels in patients with miscellaneous skin diseases, no support was found for the theory that vitamin-A deficiency is of general significance in common types of skin disease in this country. The mean of 116 I.U. per 100 ml. found in 116 dermatological cases was virtually identical with the mean of 113 I.U. found in 116 controls.

Limited support was found for the theory that secondary deficiency of vitamin A may be of some significance in certain rare skin disease. In 11 cases of Darier's disease, pityriasis rubra pilaris, or ichthyosis the mean plasma-vitamin-A level was 77 I.U. Most of the patients gave very low values at one time or another, but there were some exceptions Irregularity of the plasma-vitamin-A level in individual subjects, possibly caused by periodical exacerbations and remissions in the disease, may explain the diversity of opinion among previous workers about the reality of the fall in plasma-vitamin-A level.

In all patients with Darier's disease or pityriasis rubra pilaris given massive doses of vitamin-A concentrate the plasma-vitamin-A level rose eventually to values much above normal. In one case of pityriasis, however, the plasma-vitamin-A level did not respond until dosing had been continued daily for over two months. The possibility of interference in vitamin-A metabolism through impairment of liver function in these diseases must be borne in mind.

In two cases of Darier's disease the skin became normal, or almost normal, after treatment with vitamin A and Grenz rays. Other cases of Darier's disease showed less improvement, and in one patient the lesions were unchanged even though the plasma-vitamin-A level rose very high. Two cases of pityriasis rubra pilaris improved but remained abnormal.

Our thanks are due to Dr. H. W. Barber, Dr. G. B. Mitchell-Heggs, Dr. E. W. Prosser Thomas, Mr. A. Dickson Wright, and Mr. G. H. C. Ovens for access to patients under their care, to Dr. L. J. Harris for his valuable criticism, and to Miss A. C. Cooper for technical assistance. We are indebted to Dr. A. N. Macbeth, of Organon Laboratories, for generous supplies of vitamin-A concentrate.

STABILISATION OF PENICILLIN SOLUTIONS WITH PHOSPHATE

R. J. V. PULVERTAFT

PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY, AT KING'S COLLEGE OF HOUSEHOLD AND SOCIAL SCIENCE

THIS paper describes the stabilising effect of phosphate on the rate of destruction of penicillin by heat. It is shown that the rate of destruction depends on the concentration of the penicillin and of the phosphate; that samples of different manufacture behave differently, both in their rate of destruction and in the effect on this of the concentration of penicillin and of phosphate; and that the effect is not due to control of pH but to a specific action of the phosphate ion.

These observations arose from experiments performed by one of us (R. J. V. P.) with the assistance of Dr. Grosevitz, of the department of bacteriology, Hebrew University, Jerusalem, at No. 16 British General Hospital. It was considered possible that penicillin might act on the medium and not on the organism directly. If penicillin combined with or changed a component of the medium essential to bacterial life, the observed antibacterial phenomena might be explained.

To investigate this possibility, penicillin was dissolved in distilled water and in culture media of the same pH. On autoclaving for various periods, complete destruction was observed with water, whereas residual antibacterial activity persisted with broth, a result which gave some support to the hypothesis.

A semi-synthetic medium was then obtained from Dr. Grosevitz; it contained casein hydrolysate, tryptophane, nicotinic acid, aneurine, NaCl, $MgSO_4$, $FeSO_4$, and Sørensen's phosphate buffer. Penicillin, dissolved

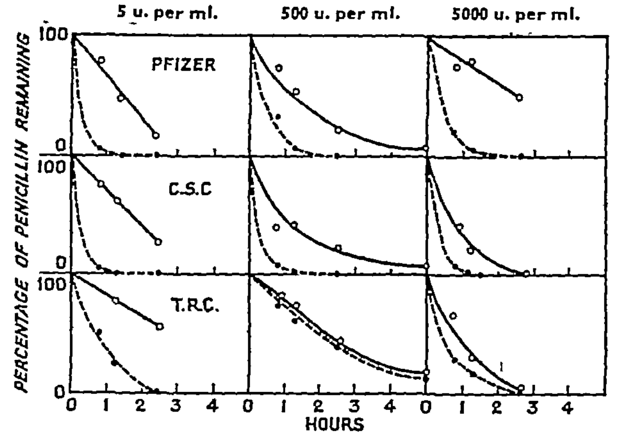

Fig. 1—Rate of destruction of penicillin at 100° C : solid line, in phosphate M/15 ; broken line, in water. Each point represents the average result of at least three experiments.

in this medium and autoclaved, maintained some of its antibacterial properties.

Each component was then tested separately ; destruction of penicillin was complete with each, except the phosphate buffer and possibly aneurine. These results were further studied by us. The results with aneurine were not confirmed. On the other hand, the stability of penicillin in the presence of phosphate was confirmed.

METHOD

Three samples of penicillin were tested : (1) Pfizer manufacture, 750 units per mg. ; (2) C.S.C. manufacture, 300 units per mg. ; and (3) T.R.C. manufacture, 45 units per mg. These products therefore contained different amounts of unknown impurities ; in sample (3) these included a fair amount of buffering agents. There is no proof that the antibacterial agents in the three products were identical.

Titration of penicillin activity was performed by the technique of doubling dilutions in the following medium :

Peptone (Evans Sons Lescher and Webb)	2·0%
NaCl	0·8%
Glucose	2·0%
Andraade's indicator	

Adjusted to pH 7·6

The doubling dilution was carried out in ten or twelve tubes, which were then inoculated with one drop of a saline suspension of *Staph. aureus* (Oxford). The suspension was of an 18-hour agar-slope culture. The end-point was taken as the first tube in which growth took place and turned the indicator red. The age of the culture and the exact composition of the medium are most important for obtaining reproducible results. Titrations by this technique were frequently checked by the *plate-ring method*.

Tests on the effect of heat were all carried out at pH 7·0, either in Sørensen's phosphate buffer mixture or in distilled water. The pH of even freshly distilled water varies considerably ; it is usually acid, but different samples for use in making up penicillin solutions, taken from different laboratories, had pH values varying from 5·5 to 9·5. All samples used in the experiments described below were adjusted to pH 7·0 after a short period of boiling.

Most of the experiments were carried out at 100° C in a constant-level water-bath. In certain tests phenol red was added as an indicator to detect changes in pH. The pH remained constant with all buffered solutions, including the most dilute ; with distilled water the pH sometimes rose slightly but never more than 0·2 unit. The solutions were always heated in containers of non-soluble glass.

RESULTS

Destruction of Penicillin at 100° C in Water and in Phosphate.—A buffer concentration of *M*/15 was arbitrarily selected for these experiments. The rate of destruction of solutions of penicillin of different concentrations is shown in fig. 1. It will be seen that, in distilled water, the rate of destruction depended on the sample *of penicillin and on its concentration. The Pfizer* sample was slightly more stable at higher concentrations, the C.S.C. sample equally stable at all concentrations, and the T.R.C. sample much more stable at intermediate concentrations.

In phosphate solutions all samples and all concentrations showed increased stability, the degree of destruction again depending on the sample and its concentration. At 5 units per ml. the T.R.C. sample was most stabilised, and the Pfizer and C.S.C. samples were less so and equally. At 5000 units per ml. the Pfizer sample was most stabilised, and the C.S.C. and T.R.C. samples were less so and equally.

Effect on Stability at 100° C of Various Concentrations of Phosphate.—The results, summarised in fig. 2, show that, though the pH was 7·0 in all instances, the effect of variations in the concentrations of phosphate differed considerably with the different samples. In the Pfizer and T.R.C. samples there was an optimal concentration, above and below which there was greater destruction of penicillin. In the C.S.C. sample the optimal concentration was not reached, all concentrations below the highest tested showing greater destruction. The optimal concentration of phosphate for each sample was as follows :

Sample	*5 u./ml.*	*5000 u./ml.*
Pfizer	*M*/13	*M*/30
C.S.C.	>*M*/3	>*M*/3
T.R.C.	*M*/100	*M*/100

Experiments with other salts showed that the effect was not produced with any of the following ions: K, Na, Mg, SO_4, Cl. The stabilisation by phosphates, therefore, is not due to its control of the pH and is a specific action of the PO_4 ion. The stabilisation originally

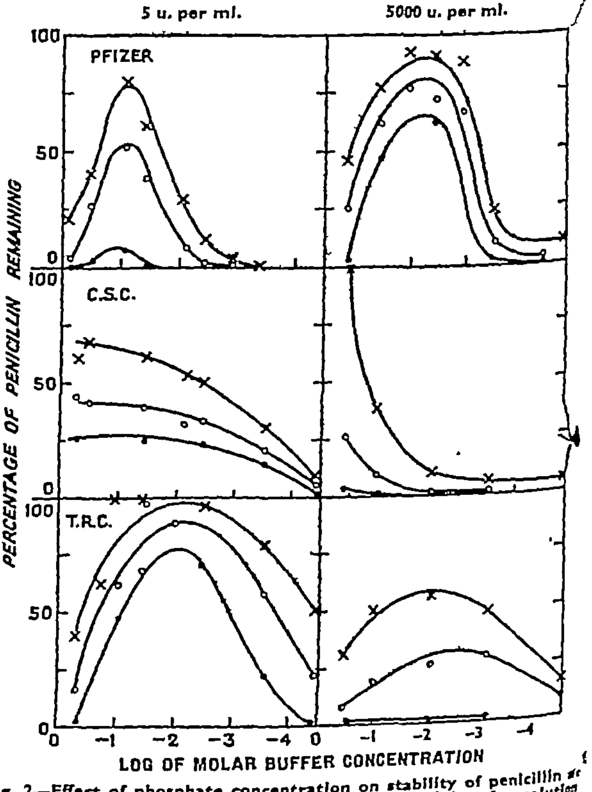

Fig. 2—Effect of phosphate concentration on stability of penicillin at 100° C. Curves represent amount of penicillin remaining after solution has been kept at 100° C for different times : X, 50 min. ; O, 75 min. ; ●, 150 min. Each point represents the average result of at least three experiments.

served with culture media is probably to be explained the phosphates contained in them.

Other Results.—(1) It has been suggested that *glucose* creases the rate of destruction of penicillin in solution. his would be surprising, since glucose solutions are ightly acid, and penicillin is more stable in acid solu-ons. Experiment confirmed this supposition; peni-llin in 5% glucose, with a pH of about 5·0, was slightly ore stable than the same solution with the pH adjusted 7·0 with soda. With phosphate buffer at pH 7·0 the ate of destruction was greatly reduced; the rate of estruction at pH 7·0, in the presence or absence of hosphate, was the same in these experiments as in hose without the addition of glucose. Glucose as such therefore without effect on penicillin.

(2) Certain samples of synthetic *rubber* destroy peni-illin. It was found in one experiment that, at 37° C, 0% was destroyed in water after three days, whereas nly 30% was destroyed in the presence of *M*/15 phos-hate. This preservation, however, did not always take lace. For example, if the rubber tube was cut into mall pieces, thereby greatly increasing the surface of ubber in contact with the penicillin, no preservation was observed.

(3) At 37° C the rate of destruction of penicillin is very slow. Nevertheless, it was possible to show, in dilute solutions, an increase of stability in the presence of phosphate, though it was not so great as at 100° C.

DESTRUCTION OF PENICILLIN AT 100° C IN PHOSPHATE AND IN WATER (% DESTROYED AFTER 10 MINUTES, BY INTRA-POLATION FROM FIG. 1)

Pfizer ..	35	5	25	5	30	3
C.S.C. ..	40	3	50	15	40	10
T.R.C...	15	3	5	5	15	5

PRACTICAL APPLICATIONS

The stability of samples of penicillin as now manufactured is much higher than previously thought, and even at 37° C destruction is comparatively slow. Nevertheless, the addition of phosphate, especially to dilute solutions such as are used for local application, makes it possible to preserve the potency of the penicillin for long periods at room temperature—i.e., without having to keep the solution in the refrigerator.

The fact that phosphate reduces the rate of destruction of penicillin by rubber may also be of some practical value. Penicillin solutions may be in contact with rubber for a considerable period in apparatus used for continuous parenteral administration, and the addition of phosphate may decrease the loss of activity of the penicillin.

In our view, however, the most important application of our findings is the possibility of sterilising solutions of penicillin with minimal loss of activity. Certain organisms, notably *Ps. pyocyanea*, are apt to grow in solutions of penicillin kept for a short time, even in the refrigerator. We have carried out tests which show that it is possible completely to sterilise solutions of penicillin, heavily infected with *Ps. pyocyanea*, by boiling for ten minutes. By intrapolation from fig. 1, it can be shown that, in this time, there is only very slight loss of activity if phosphate is present (see table).

SUMMARY

Phosphate stabilises penicillin solutions at 100° C to a considerable extent.

The degree of stabilisation and the optimal concentration of phosphate depend on the sample of penicillin. They do not depend on the amount but presumably on the nature of the impurities present in these samples.

It is possible to sterilise solutions of penicillin by boiling in the presence of phosphate, with only very small loss of activity.

Phosphate appears to decrease the rate of destruction of penicillin by some samples of synthetic rubber.

A SYNDROME SIMULATING ACUTE ABDOMINAL DISEASE

B. W. Goldstone
M.B., B.Sc. Lond., F.R.C.S.E.
LATE MAJOR R.A.M.C.

H. S. Le Marquand
M.D. Lond., F.R.C.P.
PHYSICIAN TO THE ROYAL BERKSHIRE HOSPITAL, READING;
LATE MAJOR R.A.M.C.

The purpose of this article is to describe a series of cases which at first appeared to be acute abdominal conditions. The patients were European Servicemen in a military hospital in West Africa. Careful clinical analysis of the first few cases showed that the signs did not correspond to those of the usual abdominal emergencies. Without surgical interference the illness almost always subsided. We soon learned to recognise the features of what we think is a new syndrome, and spontaneous improvement in some cases justified the diagnosis. The cases were investigated, and the results are tabulated below. Some of the more illustrative cases are described in detail.

TYPICAL CASE-RECORDS

Case 1.—Male, aged 20. This was the first case of the series. He was sent into hospital with a diagnosis of acute cholecystitis. He had severe pain in the right upper abdomen and the right shoulder, which came on in the course of a few hours. Rigidity and tenderness were present in the right upper abdomen; the rigidity was extreme, the tenderness only moderate. The temperature was 100° F, the pulse-rate 80 per min., and the respirations were 20 per min. No other physical signs were found.

The diagnosis rested between perforated peptic ulcer and pleuropneumonia. The gradual onset and the pyrexia did not support the former diagnosis, and there were no signs of the latter. We felt justified in waiting a few hours, and by then a remarkable improvement had occurred; pain, pyrexia, and physical signs were rapidly subsiding. Twenty-four hours after admission his condition was almost normal. On the 3rd day he had a slight recurrence of pyrexia, which subsided in 24 hours. Radiography in the early stages showed normal lung fields, but the right diaphragm moved less than the left; the gall-bladder was radiologically normal. No malarial parasites were found in the blood.

Case 2.—Male, aged 35, sent into hospital with a diagnosis of perforated duodenal ulcer. Several hours previously he had been gradually overcome by very severe pain in the right upper abdomen, the right side of the neck, and the right shoulder. The pain was still present on admission, with great pain, rigidity, and tenderness in the right upper abdomen. Immediate radiography showed normal lung fields, but the respiratory excursion was limited on the right side. Considerable hyperalgesia to pinprick was present over the right subcostal region, the right side of the neck, and the right shoulder. Within 10 hours he had so much improved that there was now no question of an acute abdominal emergency, and within 2 days he had recovered. Undoubtedly we would have operated on this man if we had not previously seen case 1, because the resemblance to a case of perforated ulcer was striking. However, immediate radiography had shown no sign of gas beneath the diaphragm.

Case 4.—Male, aged 19, rescued unconscious from a swimming-bath and sent to hospital as half-drowned. Two days previously he had complained of pain radiating up the chest on both sides of the sternum. This had been severe enough to keep him awake, but his medical officer could find nothing abnormal in the chest. Two days later he felt well enough to bathe. In the water he became unconscious and after his rescue artificial respiration was given because he was thought to be half-drowned. As he recovered he repeatedly clutched at his abdomen as though in great pain, and it was noted that generalised abdominal rigidity and tenderness were present. In hospital shortly afterwards he showed considerable general abdominal rigidity and moderate tenderness, most marked over the whole of the right side of the abdomen, but especially in the right upper quadrant. The temperature was 98° F, the pulse-rate 82 per min., and the respirations 24 per min. There were no other physical signs, except restricted chest movement.

The diagnosis of perforation was so strongly suggested that it was only after very careful consideration that we decided to watch his progress. During the next 10 hours he improved so rapidly that he was able to sit up and read, and the physical signs regressed correspondingly. The temperature was now 99° F, the pulse-rate 72 per min., and the respirations 18 per min. Convalescence was uneventful. Investigation showed a white-cell count of 10,000 per c.mm.: 75% polymorphs. The cerebrospinal fluid was normal. Radiography of the chest was normal.

CASE 11.—Male, aged 32, sent in with a diagnosis of perforated duodenal ulcer. For several months previously he had suffered from boils, and for several years there had been occasional pain in the right iliac fossa, suggesting chronic appendicitis. For 19 hours before admission he had gradually increasing pain to the right of the umbilicus. On admission the temperature was 99° F, the pulse-rate 100 per min., and the respirations 20 per min. Severe pain and almost board-like rigidity, with moderate tenderness, were present over the whole of the right abdomen and flank. There was no hyperalgesia, and liver dullness was normal.

We thought that this case was identical with the others of the series. Three hours later the pain was less, and the patient was asleep; but the temperature had risen to 102·6° F, and rigidity and tenderness were present only in the right iliac fossa. In view of the history suggesting chronic appendicitis, exploration was considered essential. Operation revealed no adequate cause for the severe abdominal symptoms. The appendix was removed. It lay in the pelvis and showed chronic fibrosis, with no sign of acute inflammation. Seven hours after the operation the temperature was 99·4° F, the pulse-rate 88, and respirations 20 per min. There was hardly any abdominal pain. The white-cell count was 17,500 per c.mm.: 78% polymorphs. Recovery was uneventful, except for pyrexia and slight right upper abdominal pain, lasting a few hours on the 2nd and 5th days after the operation.

FEATURES OF THE SYNDROME

(1) Gradual onset of symptoms, rising to a peak in a few hours. (2) Pain in the right upper abdominal quadrant, sometimes spreading to the whole of the right side of the abdomen and loin. (3) Considerable rigidity with relatively less tenderness in the same areas

Case	Age (yr.)	Diagnosis before admission	Symptoms before and on admission	Signs and symptoms on admission	Results of investigations*	Progress
1†	20	Acute cholecystitis	Pain developed in 6 hr. in rt hypochondrium and rt shoulder	T. 100° F, P. 80, R. 20, extreme rigidity in rt upper abdominal quadrant	Cholecystogram normal	Signs and symptoms almost disappeared in a few hours, and recovery in 5 days
2†	35	Perforated duodenal ulcer	Severe pain in rt side of abdomen and rt shoulder developed in 7 hr.	Rigidity and tenderness in rt upper abdominal quadrant; rt shoulder very painful	Sputum normal	Rapid improvement in 10 hr. and recovery in 8 days
3†	25	No diagnosis	Severe pain in rt chest radiating to rt shoulder and then to rt upper abdominal quadrant	T. 99° F, P. 88, tenderness in rt upper abdominal quadrant	..	Recovery in 5 days
4†	19	Half-drowned	2 days' pain in lower chest, sudden onset of severe general abdominal pain	T. 98° F, P. 82, R. 24, rigidity and tenderness in rt upper abdominal quadrant	Cerebrospinal fluid normal, white-cell count 10,000 per c.mm. No pathogenic organisms in stools	Improved in 5 hr. Recovered in 6 days
5	29	Malaria or chest condition	No history of boils; 9 hr. pain in rt lower ribs and upper abdomen	T. 101° F, P. 98, R. 28, tenderness and rigidity in rt upper abdominal quadrant	..	Recovery in 48 hr.
6	39	? Gastric ulcer	Boils for 9 weeks. Previous similar abdominal attack a few weeks before. Pain for 48 hr.	T. 98·4° F, rigidity of rt upper abdominal quadrant	..	Rapid recovery in 9 hr.
7	40	Acute perforated appendix	48 hr. malaise, 6 hr. epigastric pain, no boils	T. 102·8° F, P. 104, rigidity and tenderness of rt upper abdominal quadrant	..	Improved in 12 hr. Relapsed on 5th day. Recovery in 7 days
8	26	? Hepatitis	Boils for a few weeks, 15 hr. pain in rt upper abdomen and in back	T. 101° F, P. 90, boils over sacrum, rigidity and tenderness in rt upper abdominal quadrant	Hæmolytic *Staph. aureus* grown from pus	At first improved, later rt perinephric abscess evacuated
9	25	? Pleurisy ? Cholecystitis	No boils, 30 hr. abdominal pain becoming localised in rt upper quadrant	T. 100° F, P. 80, rigidity, tenderness, and hyperalgesia in rt upper abdominal quadrant	Cholecystogram normal, no pathogenic organisms found in fæces	Later had transient pain in shoulder and chest and pain in loin. Recovery in 4 days
10	21	No diagnosis	No boils, 9 days' pain in rt upper abdominal quadrant with pyrexia	T. 101° F, P. 90, rigidity and tenderness in rt upper abdominal quadrant	White-cell count 12,300 per c.mm. (polymorphs 74%), cholecystogram and fæces normal	Rigidity and tenderness moved to rt loin. Recovery in 6 days
11	32	Perforated duodenal ulcer	19 hr. abdominal pain, recent boils	T. 99° F, P. 100, R. 20, board-like rigidity and tenderness in rt upper abdomen and flank	White-cell count 17,000 per c.mm. (polymorphs 78%), cholecystogram and fæces normal	3 hr. later T. 102·6° F, nothing abnormal found at operation, uneventful recovery
13	..	Perforated duodenal ulcer	Sudden onset of severe abdominal pain (the only case in which the onset was sudden), bilateral meatal furunculosis	T. 96·8° F, P. 80, board-like rigidity and moderate tenderness in rt upper abdominal quadrant	Cholecystogram and fæces normal	Rapid recovery in 5 hr.

---

* In every case the following investigations were carried out, with the results as stated:
Urine: No abnormal constituents, culture sterile.
Radiography of chest: Lung fields normal; in some cases movement of rt diaphragm was restricted.
Blood film: No malaria parasites found in repeated examinations.

† History of boils not inquired into.

Case 12 was not included in the table as detailed notes were lost (see text) as the pain. (4) There is usually diminished movement of the right side of the chest and diaphragm, sometimes associated with shoulder pain. (5) There may be a rapid change in the symptoms and signs and particularly a change in the situation of pain and rigidity. (6) Spontaneous rapid improvement in most cases.

DIFFERENTIAL DIAGNOSIS

Acute Surgical Conditions

In our cases, when observation was justifiable, the rapid improvement excluded a surgical emergency; but when first seen a difficult problem was presented.

(1) *Perforated peptic ulcer* was excluded because the onset was gradual, often with pyrexia; liver dullness was not impaired; and subphrenic gas was not shown radiologically.

(2) *Appendicitis* was excluded because the signs were as a rule most prominent in the right upper abdominal quadrant, and the usual sequence of appendicitis symptoms—i.e., umbilical pain, nausea or vomiting, followed by pain in the right iliac fossa—was never seen.

(3) *Gall-bladder disease* and *acute pancreatitis* were excluded because these diseases are uncommon in persons of military age, there was no previous history suggesting gall-stones, and cholecystograms were subsequently negative.

Tropical Diseases

(1) *Malaria.*—In every case repeated blood examination failed to find the malarial parasite.

(2) *Amœbic hepatitis.*—The course of the illness and the failure to find amœbæ in the stools excluded this disease.

Other Medical Conditions

(1) *Acute lung disease.*—Clinical and radiological signs of chest disease were absent.

(2) Unusual *virus disease of the cord.*—Speedy recovery excluded this possibility, and the cerebrospinal fluid in case 4 showed no abnormality.

(3) *Infective hepatitis.*—Jaundice was absent and the liver was not enlarged.

DISCUSSION

Reference to cases 1, 2, 3, and 9 (see table) shows that the abdominal symptoms were accompanied by shoulder pain, and this suggests a lesion in relation to the diaphragm. Investigations excluded chest disease and all likely causes below the diaphragm, and we could not think of an explanation. At this point we saw the following case, which provided a hypothesis.

CASE 8.—Male, aged 26. On May 18 he complained of general malaise. Two days later he had right subcostal pain, and his temperature was 101·4° F. Next day he was admitted to hospital. His temperature was 101·4° F and his pulse-rate 90 per min. Right subcostal pain and tenderness were present. Corresponding rigidity was present, without hyperalgesia. There was some pain on pressure in the loin. At this stage we considered that the patient fell into the same group as the rest of the series.

On the 22nd the symptoms and signs improved, but the temperature rose to 103° F. During the next week his condition slightly improved, but pain persisted. Investigations showed a white-cell count of 21,000 per c.mm., normal urine, and sterile blood-culture. As the pyrexia continued, sulphathiazole 9 g. was given. Soon afterwards rigidity disappeared, and on June 7 a hard knobbly mass could be felt in the position of the right kidney. A diagnosis of perinephric abscess or renal carbuncle was supported by (*a*) slight scoliosis with concavity to the right; (*b*) absence of the right psoas shadow on radiography; and (*c*) defective filling of the lower calyces of the right kidney in an intravenous pyelogram.

On the 10th the right kidney was exposed by Mayo's incision. Zuckerkandl's fascia was incised, and there was a small gush of pus, which culture showed to contain a pure growth of *Staph. aureus*. This fascia and the perinephric fat were fused into a cardboard-like mass, in which a window was cut to expose the lower half of the kidney. The kidney was found to be fixed by strong adhesions into this diseased perinephric fat. The wound was sewn up with a large drain to the perinephric space. A few days after the operation discharge of pus became profuse and grew the same organism as before in pure culture. Recovery was uneventful. Histological examination of the excised tissue showed "great thickness of collagen fibres interspersed with numerous fibroblasts: there were numerous foci of small cells, with a few polymorphs suggesting multiple early abscess formation."

Clearly this was a case of staphylococcal disease of the perinephric fat. Similar cases have been described by Ryle (1936) among others. This case suggested to us the possibility that staphylococcal perinephric infection was the underlying cause in all our series, though not usually reaching the stage of abscess formation. The argument in favour of this view is as follows. Staphylococcal disease affecting the subcutaneous tissue ranges in severity from a pimple to a carbuncle. It is usually subacute, with an indolent spread, tending to resolve spontaneously. These features are reflected in our cases: sometimes there is a history of boils (cases 6, 8, 11, and 13) and usually a preliminary period of malaise which would correspond to the subacute development of the infection in the relatively silent area of the perinephric fat (cases 4, 6, 7, and 10). The range of severity of staphylococcal infection corresponds to the range shown by our series, which extends from the high temperature and long course in cases 7 and 10 to the rapid improvement of cases 3, 6, 9, and 13. Spontaneous resolution is shown by all the cases except case 8. This tendency is also well illustrated by case 12, full particulars of which cannot be included in our table because the notes were lost. The patient was seen a year before the other cases and showed a continuous swinging temperature for some weeks, with right epigastric rigidity. Later, fullness developed in the right loin, and the psoas shadow was absent on radiography. We diagnosed perinephric abscess with confidence, but 2 days before the date fixed for operation the temperature fell and recovery was spontaneous.

Suggested Explanation of the Acute Symptoms.—There is a consensus of opinion that abdominal rigidity results from a lesion of the peritoneum only. It is easy to imagine a staphylococcal lesion spreading slowly in the silent perinephric fat until the peritoneum is suddenly reached, when dramatic symptoms will develop in the course of a few hours. There is an essential difference between confirmed cases of staphylococcal perinephric abscess and the perforating lesions of appendicitis and peptic ulcer, in that perinephric abscess does not perforate into the peritoneal cavity. In fact, a perinephric abscess will rather present beneath the skin of the back. A perforating lesion gives rise to continued rigidity and tenderness while it spreads, because more and more nerve-endings are involved, but in retroperitoneal infection we have a localised area of inflammation on the posterior aspect of the peritoneum, quite unlike the spreading peritonitis of the perforative lesion. Now we can suggest a reason why the rigidity and tenderness may disappear rapidly in our cases: it is because adaptation to sensory stimuli develops quickly in the nerve-endings of this limited area of peritoneum (Adrian 1928).

The origin of shoulder pain must be discussed (cases 1, 2, 3, and 9). The upper portion of the kidney lies upon the dorsal part of the diaphragm, which is derived from the 4th cervical myotome; hence this part of the diaphragm is innervated from cervical 4, and lesions of its covering peritoneum are referred to the distribution of the supraclavicular nerves (C3 and C4). This fact is well known in surgical practice and has been confirmed by the experimental work of Capps (1932); but in case 9 the chest pain is of special interest because the site of the pain was over the 2nd right intercostal space—i.e., within the zone of the supraclavicular nerves.

We have stated why we think that this syndrome is due to perinephric staphylococcal infection, but several objections to this hypothesis are evident:

(1) Why does it develop on the right side only?

(2) Why does it develop so often in West Africa, so rarely in U.K.?

(3) Might the syndrome rather be due to an unusual type of epidemic ?

We cannot say why the right side only is affected, but the following case is pertinent.

Male, aged 38, admitted with the diagnosis of left lumbar fibrositis of 6 weeks' duration. He had dull pain and some tenderness in the left loin and back, shown at operation to be due to a large left perinephric staphylococcal abscess containing at least 1 pint of pus. There were no signs of peritoneal involvement. This suggests that left-sided perinephric infection may not give rise to the syndrome we have described.

The second query is easily answered. Staphylococcal disease is not only very prevalent and virulent in the Forces in West Africa, but also it takes unusual forms.

As for the third query: is there any evidence that these cases were an infective epidemic ? The sex and age-groups give no evidence, as the patients were members of the Forces and from widely separated units. However, it must be admitted that almost all our cases occurred from April to August, 1944.

There is one further point of interest (see case 11 in the table). Most surgeons, and this includes one of us, have at some time operated in England in full expectation of discovering an acute peptic perforation, only to be surprised by completely normal findings followed by spontaneous recovery. Are these puzzling cases examples of the syndrome described in this article ? We suggest that all such cases should be examined with this syndrome in mind.

SUMMARY

A new abdominal syndrome is described. It consists in right upper abdominal pain and rigidity with pyrexia. It comes on in a few hours and simulates in many cases a perforative lesion. Spontaneous recovery is the rule.

Of 13 cases here reported 1 eventually developed a perinephric abscess.

It is suggested that the cases which recovered spontaneously were abortive forms of perinephric staphylococcal infection. Abortive perinephric staphylococcal infection may be common in the silent perinephric fat but symptoms do not arise unless the lesion touches the peritoneum.

Cases simulating perforated peptic ulcer, but with negative operative findings, are not uncommon. They may be of the same type as those described here.

Acknowledgment is due to Lieut.-Colonel J. A. W. Segerdal, R.A.M.C., for permission to publish these cases. We wish to thank Major J. C. G. Whitelaw, R.A.M.C., pathologist, and Captain T. E. Broadbent, R.A.M.C., radiologist, for coöperation and help.

Ryle, J. A. (1936) Natural History of Disease, New York and London, p. 224.

" . . . Mr. Bevan, throughout the proceedings in committee, firmly set his face against any proposals that might tie his hands. He has asked for virtually unlimited powers, and obtained them, not because he wants to be a health dictator, as his opponents claim, but because that is the last thing he dare be. It would need an establishment far beyond anything the Ministry of Health could hope to acquire if he were to attempt to oversee the detailed running of the health services. But until they are running, or at least until the structure has been set up, no-one can tell what powers will be necessary and what can be discarded in practice. Wide powers are to be taken in order to achieve flexibility, not excessive centralisation. That, at least, seems a reasonable interpretation of this enabling Bill, which, in an entirely new field of activity for the State, possibly leaves more undefined, and introduces more ambiguities, than any comparable measure. . . . The National Health Service Bill probably sets up the best structure that could be devised for providing such a very personal service for the people. But until it is certain that it will work as Mr. Bevan intends it to work, final judgment will still have to be reserved."—*Economist*, August 3, p. 163.

SPOROTRICHOSIS RESEMBLING DIPHTHERIA

REPORT OF AN UNUSUAL CASE

H. STANLEY BANKS
M.D. Glasg., M.R.C.P., D.P.H.
MEDICAL SUPERINTENDENT, PARK HOSPITAL, L.C.C.

SPOROTRICHOSIS is a rare disease produced by a fungus of the genus sporotrichum. The tissues primarily invaded have usually been subjected to some form of trauma or devitalisation, the organism being a saprophyte with relatively feeble powers of parasitism. The site of entry is most commonly the skin of the hand; invasion of mucosa is usually secondary, but a conjunctival lesion may be primary (De Beurmann and Gougerot 1912, Welder and McCullough 1914). The type of lesion usually produced is a granuloma of the subcutaneous tissue in the form first of nodules and later of gummata, abscesses, or ulcers. These are often distributed along the course of lymphatics leading from the primary lesion. They may, however, be disseminated widely by general blood-stream infection. Where the skin is soft, as in the face, the ulcers are usually echthymiform cup-like depressions (fig. 1). Foerster (1924) refers to a typical cup-shaped ulceration of the mucosa overlying the anterior part of the nasal septum. In the mucosa of the palate, pharynx, and conjunctiva the nodular character of the lesion is usually preserved in the form of small papillomatous or gummatous vegetations or yellowish follicular spots 1–2 mm. in diameter set in a greyish yellow layer of mucopus (De Beurmann and Gougerot 1912). I can find no reference in the literature to mucosal lesions closely resembling diphtheritic membrane, and for that reason the following case is recorded.

CASE-RECORD

A female infant, aged 11 months, was admitted to Park Hospital on Feb. 28, 1944, certified as having nasal diphtheria. She had been ailing four weeks, the symptoms being nasal discharge, nausea, recurrent vomiting, and cough. The cough had become croupy a week before admission.

On admission the child was apyrexial and not particularly toxic. The fauces showed superficial ulceration, with thin membranous exudate covering the uvula and a small area of fauces and palate on each side of it. There was neither œdema nor redness round this lesion. The submaxillary glands were palpable, but there was no circumglandular œdema. The anterior nares and a small adjoining part of the upper lip were excoriated. There was a thin bloodstained nasal discharge but no definite membrane in the nares. The distinctive presenting sign was in the left eye: a thin soft yellowish sheet of membranous exudate, with well-defined margins, lining the whole of the palpebral conjunctiva of the lower lid. Beyond the margin of this membrane the fornix of the conjunctiva was red and œdematous. The cornea was slightly hazy. The right eye showed a somewhat similar condition, but the exudate on the palpebral conjunctiva was thin, flimsy, and less extensive. The voice was hoarse.

Clinically, the case appeared to be one of anterior nasal, uvular, ocular, and possibly laryngeal diphtheria. Swabs were taken from the three available sites, and it was noted that the membrane did not wipe off from the uvula and conjunctivæ, nor did it bleed. Diphtheria antitoxin 60,000 units was injected intravenously. The eyes were irrigated with saline and 20% 'Argyrol' instilled. All three swabs were reported next day to be negative for *Corynebacterium diphtheriæ* and to give a profuse growth of hæmolytic streptococcus. The swabs were repeated on the 29th with the same result, except that, on this one occasion, virulent *C. diphtheriæ* of gravis type was grown from the nose (probably a secondary infection picked up in the ward). Because of the hæmolytic streptococci the child was given sulphathiazole 0·5 g. four-hourly.

On March 1 the membrane in the fauces had spread considerably over both sides of the soft palate, uvula, and fauces, but without surrounding œdema or redness and without fœtor. It was firmly adherent but could be broken up on forcible swabbing without bleeding. The conjunctivæ in both yes, but particularly the left, were very red and swollen and howed shreds and patches of greyish yellow exudate but not now a continuous sheet of membrane. The nares were more xtensively ulcerated and exuded hæmorrhagic discharge. A swab from the palatal membrane on this day was negative or *C. diphtheriæ*, Vincent's organisms, and fungus in smears, but gave a good growth of hæmolytic streptococcus type 25.

On the 3rd the membrane covered the whole of the soft palate, still without surrounding redness or œdema, and without periadenitis. In both eyes there was now a brown-stained pellicle over the cornea. Although by this time there was much evidence against a diagnosis of diphtheria, for safety additional diphtheria antitoxin 60,000 units was given intravenously, and sulphathiazole was continued in the same dosage.

On the 4th the eyes were seen by Mr. M. Shaw, who reported "central bilateral corneal ulceration, extensive in the left eye; severe ulceration of palpebral surfaces of eyelids; conjunctivæ and eyelids œdematous." A blood-count showed white cells 13,000 per c.mm. (polymorphs 66%, eosinophils 0·5%, basophils 0·5%, lymphocytes 25·5%, monocytes 7·5%).

On the 6th the membrane in the throat extended over most of the palate, fauces, uvula, and posterior pharyngeal wall as far as could be seen. There was a hoarse cough, with occasional slight stridor on inspiration, but no recession of the chest wall. The membrane had been completely washed off the eyes, leaving corneal ulceration and opacity and severe conjunctival congestion. A throat swab and smear on this day showed no *C. diphtheriæ*, Vincent's organisms, or fungus, but only a pure growth of hæmolytic streptococci. A culture was put up for fungus. The hæmolytic streptococcus type 25 previously isolated was reported to be partially resistant to sulphanilamide but sensitive to sulphathiazole.

On the 9th the membrane in the throat and pharynx was still as extensive as ever and still without accompanying œdema. The ulceration of nares and upper lip was more extensive. The eyes exuded sticky seropurulent discharge, and there were an extensive left and a smaller right corneal opacity. There were stridor and slight recession at times. A new feature present was a small area of ulceration of the right auditory meatus and pinna, with seropurulent discharge (fig. 1).

On the 13th sulphathiazole treatment was changed to sulphadiazine 0·5 g. four-hourly. On the 15th the culture for fungus, set up on the 6th, was reported to have grown *Sporotrichum schencki* (fig. 2). Sulphonamide medication was stopped, and pot. iod. gr. $1^1/_2$ four-hourly substituted. The mucosa of mouth and throat was painted with Mandl's paint. The temperature, which had been practically normal throughout, now began to rise slightly.

On the 17th a large piece of the palatal membrane was examined for sporotrichum spores or mycelia in direct smear, with a negative result. Mr. Shaw reported a sloughing left cornea, and on the 18th removed the left eye. After the operation the child's condition deteriorated. By the 21st the temperature, which had been practically normal throughout, had risen to 103° F. There was still membrane on the buccal mucosa, gums, fauces, and palate; and the left eye socket showed a thick hard nodular mass in the conjunctiva of the upper lid. The child was coughing up bloodstained mucopus; and the *tips of the thumbs and circumanal region* showed superficial ulceration similar to that on the ear, nares, and upper lip. The child died on the 24th.

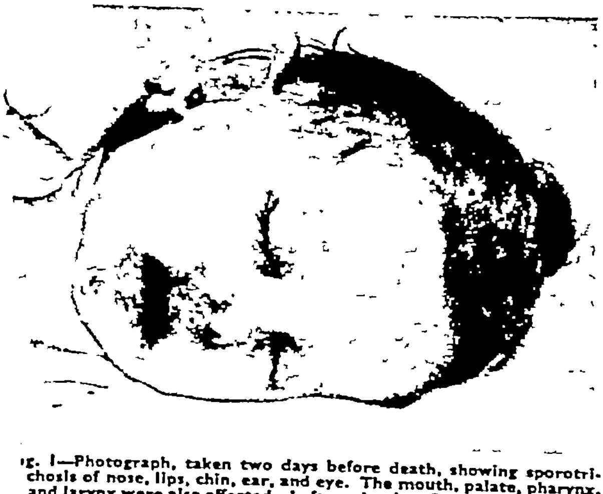

Fig. 1—Photograph, taken two days before death, showing sporotrichosis of nose, lips, chin, ear, and eye. The mouth, palate, pharynx, and larynx were also affected. Left eye has been surgically removed.

Necropsy (Dr. E. M. Young).—The *œsophagus* was covered with sticky mucopus, but there was no ulceration of the wall. *Mouth:* dense adherent membrane covered both tonsils, soft palate, and epiglottis. *Larynx:* aryepiglottic folds roughened but no ulceration. *Trachea:* purulent discharge but no ulceration. *Pleura:* no pleural fluid, no adhesions. *Lungs:* no consolidation; bronchi contained frothy mucopurulent secretion. *Heart* dilated on right side; slight excess of clear yellow fluid in pericardium. *Intestine* normal. *Liver:* a few areas of fatty degeneration. *Gall-bladder, kidneys,* and *suprarenals* normal. *Brain:* congestion and œdema but no gross lesion. *Middle ears:* both contained purulent material and necrotic bone. Culture from the exudate in the mouth gave a growth of *Sp. schencki* and of hæmolytic streptococci. Cause of death: sporotrichosis of mouth, pharynx, larynx, ear, and eyes; toxæmia.

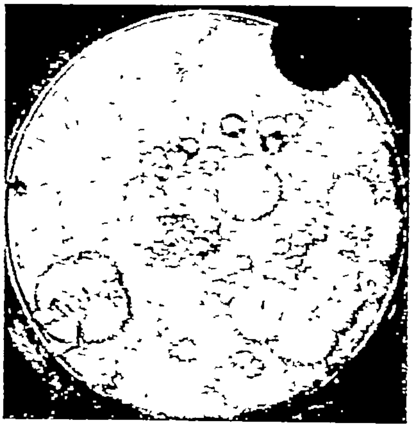

Fig. 2—Primary culture from swab of membrane on palate on 10th day after admission, showing *Sporotrichum schencki* (larger colonies) and *Monilia albicans* (smaller colonies) on Sabouraud's medium.

The left cornea removed at operation showed no distinctive histological features. The epithelial covering was denuded, and an inflammatory exudate was present, consisting largely of polymorphs, red blood-cells, and fibroblasts. In one part there was a well-marked new formation of granulation tissue. The posterior elastic lamina was not involved.

DISCUSSION

According to Jacobson (1932) sporotrichosis was first recognised by Link in 1809 and later by Montague in 1844. Schenck (1898) successfully isolated the fungus and was the first to describe sporotrichosis in the United States. De Beurmann and Ramond (1903) were the first to recognise the disease in France. Most of our knowledge of the disease is owed to De Beurmann and Gougerot (1912), whose monograph in two volumes still remains the monumental work on the subject. They describe two parasitic sporotricha but admit that these exhibit considerable pleomorphism, and that they may be merely different varieties of one parasite.

According to their description, *Sp. schencki*, on Sabouraud's medium, grows as white colonies with little tendency to pigmentation and presents a rough mountainous aspect with radiating furrows from centre to periphery; spores are few. It is the common variety in the United States. *Sp. beurmanni* commonly grows as brownish or even chocolate colonies but sometimes remains white for some days. The surface aspect is one of fine whorls irregularly crossed by crests and furrows; the spores are massed in large numbers. It is the common variety in France. There is a general tendency in recent literature to classify all parasitic sporotricha as *Sp. schencki* in honour of the discoverer. On culture, growth does not become visible for at least four days. By the eighth day the colony is about 1 cm. in diameter, and by the 24th day it may be 4 cm. or more in diameter, with a pigmented centre. Microscopically, the mycelia appear as hyaline fine branching organisms 1–2 μ in diameter. The spores are oval or oat-shaped and are attached to short lateral branches or longer hyphæ.

The fungus has been found on many types of vegetation, living, dead, and decayed—e.g., leaves, bark, barberry bush, sphagnum moss—on the fur, skin, or lesions of the natural disease in domestic and laboratory animals—e.g., cat, rat, and rabbit—and on insects—e.g., flies, wasps, and ants. It grows readily at ordinary temperature on various culture media in the open air and is resistant to sunlight. Even contaminated soil is thus a possible source of infection. Most of the human patients have been infected, from live or dead vegetation, on the site of an injury of skin or mucosa—e.g., the prick of a barberry thorn, the bite of an animal, or the sting of an insect.

Sporotrichosis is mainly a disease of adults, particularly of agricultural manual workers and housewives. In the United States 206 cases had been reported up to January, 1940, the chief occupations of the victims being, in order of frequency, farmers, gardeners, and nurserymen, housewives, industrial workers, and general labourers (Gastineau et al 1941). Most of the reported cases have been in the Mississippi and Missouri valleys of the United States and in France. The fungus, however, is known to be widespread and found in every country. In Britain 9 cases had been reported up to the year 1932 (Gray and Bamber 1932).

The disease is usually chronic. The organism can remain a saprophyte in man and invade the tissues long after inoculation. Similarly, it can persist (in the pharynx and larynx at least) several months after healing of the lesions (De Beurmann and Gougerot 1912). Prognosis in the common cutaneous lymphatic variety is good, but is grave in all mucosal lesions. Treatment with iodides is generally effective, at least in the cutaneous variety. Iodides should be given up to the limit of toleration—e.g., gr. 30–75 daily for three weeks and continued in reduced dosage for at least three months, or for six weeks after visible healing of the lesions.

The case described was of a very unusual type. Its presenting features on admission to hospital included superficial ulceration of the anterior nares, superficial ulceration and thin membranous exudate on the uvula and adjacent parts of the soft palate, and thin membranous exudate lining the whole of the palpebral conjunctiva of the left lower eyelid. The last-named lesion bore an exceedingly close resemblance to that of ocular diphtheria as previously seen by me. The absence of the typical discrete papillomatous lesions of sporotrichosis, both on the conjunctiva and on the palate and fauces, was as remarkable a feature of this case as was the presence of false membrane in the eye and palate. The only lesion which developed according to type was the cup-shaped ulceration spreading from the anterior nasal septum to the lips and side of the face. The membrane on the palate looked like the false membrane of diphtheria for days, but the absence of surrounding œdema and of periadenitis, after the membrane had grown all over the palate, made a diagnosis of diphtheria after a few days most unlikely. This was confirmed by the many negative reports on swabs from eye, nose, and throat. The one swab positive for *C. diphtheriæ*, obtained from the nose twenty-four hours after admission to the ward, was almost certainly a ward contamination, since this finding was not confirmed by earlier or later swabs, the clinical course, or the necropsy. The pathological work made it clear that the case was one of sporotrichosis complicated by a persistent infection with type-25 hæmolytic streptococcus. Whether the streptococcal infection was a factor in modifying the clinical picture or not is a matter of speculation.

The diagnosis of sporotrichosis in the absence of a typical clinical picture usually involves delay, since the organism is not commonly seen in direct smears, and the result of a culture cannot be known for five days or more. A serum test for antibody may be tried, if a suspension of sporotricha is available as an antigen. For a positive result the titre should be high, since actinomycosis may also give a positive result in low dilutions. A dilution of 1 : 800 is suggested as a typical positive result (Foerster 1924, Gaucher 1910). In the present case the diagnosis was made by culture on the sixteenth day after admission to hospital.

Treatment with potassium iodide in this case was without effect. De Beurmann and Gougerot (1912) emphasise the grave prognosis of pharyngeal sporotrichosis in contrast to that of the cutaneous lymphatic type. Surgical treatment should be avoided as far as possible. French (1941) mentions a case in a man, aged 42, who died after amputation of the hip-joint, having had the disease for 39 years. In the present case, although the prognosis was always desperate, there was no deterioration after the removal of the eye.

SUMMARY

A brief account of the rare disease sporotrichosis is given.

A case of pharyngeal, ocular, and nasal sporotrichosis is described which was unusual in closely resembling diphtheria on first examination.

My thanks are due to Dr. E. M. Young, assistant pathologist, Southern Group Laboratory, Park Hospital; Mr. M. Shaw, ophthalmologist; and Dr. L. J. M. Laurent.

PEPTIC ULCER

TREATED WITH GASTRIC AND INTESTINAL EXTRACTS

O. HUBACHER
M.D. Berne

From the Medical Ambulatory Clinic of the University of Berne, Switzerland

SINCE certain substances occurring naturally in the body—e.g., histamine—can give rise to peptic ulcer (Matsueda 1931, Friedenwald et al. 1932, Carnot et al. 1933), it is reasonable to suppose that other substances occurring naturally in the body may prevent ulcer formation. Many biologically active substances have been isolated from the intestinal tract—e.g., cholecystokinin, secretin, enterocrinin, villikinin, enterogastrone, and urogastrone. Knowledge of enterogastrone and urogastrone is due to Gray (1941), Quigley (1941), Sandweiss et al. (1941), and Ivy (1941). Enterogastrone, extracted from the intestinal mucosa, diminishes gastric secretion, decreases gastric motility, and participates in the regulation of the blood-supply to the gastric and duodenal mucosa. Thus enterogastrone can largely prevent the appearance of intestinal ulcer in dogs subjected to duodeno-ileal anastomosis and gastrojejunostomy according to the technique of Mann and Bollmann (1933). Urogastrone is a substance, analogous to enterogastrone, obtained from urine; it is found in decreased quantity in the urine of ulcer patients, and it has been assumed to represent an excretory form of enterogastrone. Good results have been obtained in cases of gastroduodenal ulcer by injection of urogastrone, but experience of administration of enterogastrone has apparently not yet been reported.

Independently of the results obtained in the United States, extracts have been prepared in Switzerland from the tissue of the stomach and the small intestine of freshly slaughtered animals. These extracts[1] are free from lipoids and proteins. The water-soluble part of the finished extract is used for injection, and the water-insoluble fraction is put up in tablets, to make possible the simultaneous administration of injections and tablets. The preparation for the treatment of gastric ulcer contains predominantly extract of stomach, whereas that for the treatment of duodenal ulcer contains principally extract of small intestine.

The treatment of gastritis, gastric ulcer, and duodenal ulcer with gastroduodenal extracts is based on the upposition that the normal functions of the stomach and the duodenum are maintained by various biologically active substances, the absence of which favours ulcer formation. In Switzerland this therapy has been not only the subject of much clinical work (Schmassmann 1944, 50 cases; Mamie 1944, 24 cases; Keiser 1945, 37 cases; Neumann 1946, 55 cases; Berther 1944, 20 cases) but also of an experimental investigation by Roulet (1945), who obtained rapid healing of histamine ulcers in guineapigs, even when the ulcerative agent, histamine, continued to be given.

The direction of attention to a new form of ulcer therapy is justified on the following grounds:

(1) The increasing incidence of gastric and duodenal ulcers.

(2) The unsatisfactory outcome of other forms of ulcer therapy, including treatment with sexual and adrenocortical hormones, whereby undesirable secondary effects (diminished potency, mastodynia, œdema, hypertension) are caused.

(3) In general practice the imposition of a strict diet is not easy, and the wish of a patient not to cease work must often be granted.

MATERIAL AND METHODS OF TREATMENT

Our experience of treatment with the robuden preparations extends over sixteen months and comprises 54 cases: 25 gastric ulcers, of which 9 were indurated; 15 duodenal ulcers, of which 1 was indurated; 3 cases of simultaneous gastric and duodenal ulcers; 7 of gastritis; and 4 tumours.[2]

The great majority of the patients were ambulant; only 3 patients were admitted to hospital for treatment. These 3 patients were given a strict diet, but the other patients were simply advised to avoid articles of food which, in their own experience, gave rise to symptoms. Most of the patients never absented themselves from their work; this feature of the treatment, together with the obviation of confinement to bed and dieting, constitutes a real advantage, especially in view of the continuing increased incidence of ulcer.

Where possible both injections and tablets were given. The total number of injections ranged from 12 to 21, given either daily or three times a week; the tablets were given at the rate of 3 a day before meals or at the rate of 6 a day, 1 tablet before and 1 tablet after each meal, for several months. In especially resistant cases the number of injections was increased to 30 or more. In the case of patients who refused the injections, or who on practical grounds could not attend daily for injection and did not wish to be admitted to hospital, only the tablets were prescribed. Patients with gastric ulcer were treated with stomach extract, and patients with duodenal ulcer were given extract of small intestine. Patients with both gastric and duodenal ulcers were treated with both extracts given alternately. Disregard of this principle by treating one such patient with stomach extract alone led to healing of the gastric ulcer in the usual time, whereas the duodenal ulcer remained unaltered.

RESULTS

In estimating the success attained, attention has been directed principally to alterations in the general subjective condition, disappearance of symptoms, and decrease in size of the ulcer niche as disclosed radiologically. Decrease in size rather than disappearance of the niche is emphasised, because experience has shown that an ulcer may escape radiological observation by becoming filled with remnants of food or as the result of œdematous alteration of the mucosa. The acidity values have been neglected, because this aspect has already been exhaustively dealt with by Schmassmann (1944), Neumann (1946), and others, and because modern work tends to assign less importance to the gastric chemical processes in regard to the diagnosis and treatment of digestive troubles. Schmassmann reported that robuden exercised a regulatory action on gastric acidity, both hyperchlorhydria and hypochlorhydria tending to return to normal.

RESULTS OF TREATMENT OF PEPTIC ULCER WITH TISSUE EXTRACTS

Diagnosis	No. of cases	On the basis of—			
		Subjective and clinical examination		Radiological examination	
		Good results	No improvement	Good results	No improvement
Simple gastric ulcer ..	16	16	0	7*	0
Indurated gastric ulcer..	9	6	3	4	5
Simple duodenal ulcer ..	14	13	1	6†	1†
Indurated duodenal ulcer	1	0	1	0	1
Gastric ulcer and duodenal ulcer	3	3	0	3	0
Gastritis	7	6	1	2‡	0
Tumour	4	0	4	0	4

* Only these 7 cases out of the total of 16 were followed radiologically.
† ,, 7 ,, ,, ,, 14 ,, ,, ,,
‡ ,, 2 ,, ,, ,, 7 ,, ,, ,,

Of the 54 cases, 33 were followed radiologically; the remaining 21 cases were examined radiologically at least once.

The table shows a lack of good response to treatment in the indurated ulcers, whilst Schmassmann (1944), Hemmeler (1944), and Mamie (1944) also reported lack of success with such ulcers. We found subjective and objective clinical improvement in two-thirds of the cases of indurated ulcer, although rather less than half of them showed radiological improvement. The suitability or otherwise of an ulcer to treatment with these extracts depends on the radiological structure of the ulcer niche rather than on its size. In 2 cases of indurated ulcer, after failure of ambulant treatment, admission to hospital and prescription of a strict diet did not lead to improvement, probably because the ulcers had caused structural anatomical changes requiring surgical intervention. In one case the persistence of subjective symptoms was due to the gastric crises of tabes. In one case of duodenal ulcer and in one of gastritis there was radiological improvement coupled with unchanged subjective and clinical symptoms; psychiatric examination disclosed a neurosis in both cases.

The time required for the treatment to produce an effect is very variable; improvement rarely took place before the tenth injection, or, if tablets alone were administered, before fourteen days. On completion of a course of injections, the tablets should continue to be taken for 2–3 months.

---

[1] 'Robuden pro U. ventr.,' 'Robuden pro U. duod,' and 'Robuden' tablets made by the Robapharm Laboratories, Basle.

[2] Abstracts of the case-records can be obtained from the author.

Secondary Effects.—Apart from occasional severe pain at the injection site, no undesirable secondary effects have been encountered; onset of fever in 2 cases was traced to the fortuitous presence of pulmonary and of oral infection. As the extracts are free from protein, activation of an intercurrent malady is unlikely.

Relapses.—Schmassmann (1944) suggested the administration of robuden tablets in the spring and autumn as a prophylactic measure; this suggestion has been taken up in many clinics and in general practice, and we also have adopted it. The period of our observations is yet too brief to permit conclusions to be drawn; but, excluding cases of indurated ulcer, we have encountered only 3 cases of relapse in sixteen months; and these were cases not submitted to this prophylactic treatment. It may be noted that the number of relapses following other earlier medical treatments was much greater.

SUMMARY

Of 54 cases treated with extracts of stomach and of small intestine 44 showed good results, the majority being subjected to radiological control. The 10 failures included 2 neuroses, 3 indurated ulcers, old scarry deformations (1 case), carcinoma (3 cases), and 1 gastric tumour. (Previous publications in Switzerland list 234 cases, of which 209 (89%) reacted favourably to this treatment.)

All the cases which benefited by this treatment showed rapid disappearance of symptoms, increase of weight, and rapid decrease in size of the ulcer niche as disclosed by radiography. Some cases of indurated ulcer reacted favourably, but others, and cases involving tumours, were not influenced.

These results were obtained without dietetic restriction or confinement to bed.

Injection of the preparations gave rise to no undesirable secondary effects apart from occasional pain at the injection site.

The administration of the extracts as tablets to supplement the injections and as prophylaxis is suggested.

I wish to thank Prof. W. Hadorn, director of the Medical Ambulatory Clinic of the University of Berne, for his advice and encouragement.

Reviews of Books

Principles of Dynamic Psychiatry

Including an Integrative Approach to Abnormal and Clinical Psychology. JULES H. MASSERMAN, M.D., division of psychiatry, University of Chicago. London: W. B. Saunders. Pp. 322. 20*s.*

THE aim of this intelligent and ambitious book is to introduce the student to the principles of modern dynamic psychiatry; a companion volume will elaborate the application of these principles to diagnosis and treatment. The book has arisen out of the author's need as a teacher to have a test to which he could refer his students for basic information; he points out that at present the beginner may "either become compulsively and sometimes morbidly intrigued with some special and narrow approach (such as the 'somatic,' 'reflexologic,' 'semantic,' or 'psychoanalytic') or he may fly from the wilderness of some of the current literature and from his own anxieties by deciding, not altogether correctly, that psychiatry is a contentious cacophony of fantastic dogmas, contradictory nosologies, and impractical theories somehow inserted into an otherwise 'scientific' university or medical school curriculum." Thus obviously aware of some of the pitfalls, Dr. Masserman has done his best to synthesise the products of his wide reading, his clinical and psychological experience, and his valuable experiments into the relationship of the hypothalamus to behaviour in the cat: the outcome is a stimulating, slightly pretentious book which students will find harder to read and much more solid and satisfying than the usual hackneyed expositions.

Psychiatry as a medical science, psychological and psycho-analytical concepts of behaviour, and the dynamics of adaptation and mental disorder make up the first part of the book: in the second a general biodynamic theory of behaviour is put forward, with frequent, sometimes critical, reference to the theory of conditioned reflexes and to psycho-analysis, from which the author's "biodynamic correlations" are largely derived. The last chapter of the work is devoted, very agreeably, to a critique of the biodynamic theory: the author puts his theory in the dock, and after fair and kindly examination of what prosecuting counsel have to say, acquits it of everything except necessary incompleteness. Appendices contain an illustrative account of the psycho-analysis of a neurotic personality, and reprinted articles on psycho-analytic formulation of the psychoses, and some principles of group communication. A bibliography of about 200 titles, and a glossary, complete the slightly exuberant book.

Postural Circulatory and Respiration Changes During Ether and Intravenous Anesthesia

TORSTEN GORDH, anæsthetist-in-chief, Karolinski Sjukhuset, Stockholm. Stockholm: *Acta Chirurgica Scandinavica.* Supplement CII. Pp. 126.

Dr. Gordh has undertaken the sort of fundamental research in anæsthetics which is still needed. The work, profusely illustrated with kymographic records, is divided into three parts. The first contains an extensive summary of the literature on the effects of ether and barbiturate anæsthesia on the circulation and respiration. (The first description of intercostal paralysis as a sign of deep anæsthesia is here attributed to Albert Miller, in 1925, instead of Snow, who described it in 1858.) The second part records the author's own researches on the rabbit, which confirm the clinical findings of every anæsthetist. Dr. Gordh demonstrates the benefit of a moderate Trendelenburg position on the circulation and respiration, and the baneful effects of anoxia and of carbon dioxide excess. In the third part the value of the head-down posture and oxygen excess in the treatment of cardiorespiratory failure during clinical anæsthesia is discussed and emphasised. English-speaking anæsthetists will be gratified to learn that such excellent fruit as this monograph has sprung from seeds sown during Dr. Gordh's visits to this country and to America.

Ocular Prosthesis

J. H. PRINCE, F.B.O.A., F.S.M.C. Edinburgh: E. & S. Livingstone. Pp. 134. 17*s.* 6*d.*

Mr. Prince sets out to describe the process by which artificial eyes may be made and fitted, and he gets to the root of his subject by a first chapter on the history and development of artificial eyes from 2500 B.C. onwards, and follows it with a chapter on the anatomy and physiology of the orbit. This second chapter needs serious revision; many random and inaccurate statements are made on the pathology and surgery of the eye and orbit, and many other statements leave one in doubt as to their true meaning. The words exenteration and evisceration are repeatedly confused, and there is an unsatisfactory diagram of the anatomy of the orbit and surrounding structures. The chapter on the principles of fitting prostheses concludes with some harrowing descriptions of how eyes may be lost. In the latter half of the book Mr. Prince is on his own ground, and here the reader will get some help on the fitting and making of artificial eyes. When this book has been revised with the aid of an ophthalmic surgeon it will fill a definite need, especially among artificial-eye makers.

Yes, doctor, a boon to patient . . . and me . . .

Hyperduric ADRENALINE is one of the new series of preparations developed from the discovery that drugs injected in the form of mucates, instead of the usual salts, such as hydrochlorides, are liberated slowly and uniformly, yielding controlled prolongation of pharmacological action. ***Hyperduric*** ADRENALINE is a solution containing 1 part of adrenaline in 1000, as mucate. It is of value in bronchial asthma and other allergic disturbances, including anaphylactic (e.g. serum) shock, besides surgical shock. The relief is observable for a period of 8 to 10 hours in patients who have previously experienced relief for periods of only ½ to 2 hours after an injection of adrenaline hydrochloride solution.

PENICILLIN

for minor infections

The imposing list of indications for penicillin therapy must not obscure the very great importance of this wholly non-toxic substance in the treatment of minor infections. Penicillin is unaffected by the presence of serum or pus, is completely innocuous to the leucocytes, and has a higher activity against the common pathogenic organisms than any other chemotherapeutic agent.

It has great value, therefore, in the treatment of septic cuts, abrasions and burns, boils, sore throats and many other every-day conditions; and may well alter the whole conception of prophylactic treatment of those minor ailments.

PENICILLIN *Glaxo*

DRY SODIUM SALT FOR INJECTION IN AQUEOUS SOLUTION

Prices subject to usual professional discount.

Colourless Flavine

● For application to cuts and wounds, 5-Aminoacridine, an all-round useful antiseptic, is now made available in water-soluble jelly form as 'Flavogel' (1 in 500).

Related to acriflavine, the bactericidal activity of this new antiseptic is a more effective aid to healing because it interferes less with the formation of granulation tissue.

Moreover, it does not stain the skin, and the slight discolouration of fabrics is easily washed out.

PRODUCT OF THE GLAXO LABORATORIES

FLAVOGEL

5-AMINOACRIDINE HYDROCHLORIDE
1½ oz. and 9 oz.

● *5-Aminoacridine is also available as a powder for making up solutions in water, isotonic saline or alcohol.*

The Peptic Ulcer

THE natural history and treatment of peptic ulcer are still two of the most important problems of medicine, and further inquiry into their environmental and economic aspects is badly needed. Already, however, such studies have begun to give useful indications. In younger people, at any rate, it seems that the mortality from gastric ulcer is related both to poverty and to employment, though in the latter case it is an inverse relationship in that a rise in employment tends to be associated with an increase in mortality, perhaps because of the extra stresses and strains of work as against the leisure of unemployment! As MORRIS and TITMUSS[1] have written, "it is hard to resist the conclusion that urban life nowadays is an ideal soil for the flowering of the ulcer temperament." Psychosomatic factors concerned in ulcer formation have had much attention, and such observations as those of WOLFF and WOLF on their patient "Tom" have demonstrated beyond question the extreme changes that the gastric mucosa may show under emotional stimuli, particularly those associated with feelings such as frustration or resentment. The influence of emotion on the "psychic secretion" of gastric hydrochloric acid, and on the tone and motility of the stomach, has also been demonstrated. For instance, MCCARTHY,[2] at the Mayo Clinic, finds that mice which show great enthusiasm at the sight of food also have a greater gastric secretion than those apparently indifferent to food. From this work he concludes, with others, that a simple gastric test-meal without correction for dilution with duodenal juice, and without some separation of the different phases of secretion (nervous and chemical), is liable to be fallacious. There are, as he says, many possible causes of high acidity, such as excessive psychic stimulation, increased gastric or intestinal chemical excitation, imperfect regurgitation from the duodenum, and even excessive absorption of water. Both the psychic and the intragastric chemical phases of secretion are controlled largely by the vagus, and his experiments in mice show that they can be influenced by vagotomy. This operation greatly reduced gastric acidity in his mice, and on the view that ulcer healing demands control of gastric acid it has already been tried in man for the treatment of peptic ulcer.

One of the many important investigations into the chemical control of acidity has been the work on the isolation of enterogastrone, to which an article by Dr. HUBACHER in our present issue again calls attention. This investigation, developed during in the war, was based on the familiar fact that fats in the intestine have an inhibitory effect on the pepsin-secreting cells in the stomach, and that the same inhibition takes place in gastric pouches deprived of any nerve-supply. By making an extract of intestinal mucosa which had been in contact with fat, KOSAKA and LIM[3] produced a substance to which they gave the name enterogastrone, which inhibited gastric secretion by a humoral mechanism. Later IVY and his co-workers studied this substance, and purified it considerably, so that it has been used (as has a similar substance found in normal urine and called urogastrone) in the treatment of patients with peptic ulcer. Now Dr. HUBACHER is able to report results of the treatment, with gastroduodenal extracts, of 54 patients suffering from gastric or duodenal ulcers. The idea behind this treatment is that normal gastric and duodenal function is maintained through the stimulus of various biologically active substances (such as enterogastrone) which are present in healthy mucosa and whose absence favours ulcer. The extracts used by Dr. HUBACHER are in his opinion specific in the sense that he was successful only when stomach extract was used for gastric ulcer, and small-intestine extract for duodenal ulcer, and not if the extracts were reversed. Of his 54 patients, mainly ambulant, most were given treatment by injection as well as by mouth, and did not leave off work or abide by any strict diet; and of these 54, all but 10 showed "good results" over sixteen months.

Such reports necessarily call to mind the similar results obtained at first by injection of histidine, which has not, however, substantiated its claim to be a specific remedy. As a correspondent points out on p. 272, the last word in these matters rests with the statistician, and before drawing conclusions about the treatment of peptic ulcer a great deal of attention must be paid to controls. In few other fields of therapeutics is it so difficult to judge the efficacy of alternative forms of treatment, and any period of observation of less than five years is open to the criticism that natural remissions are characteristic of peptic ulcer, and that long periods of healing and freedom from symptoms may follow the most varied forms of treatment or none at all. The facts as known at present certainly do not justify discarding the proved aids of rest, diet, and regimen, and while we continue to believe in a neurogenic factor in causation, we must recognise the effect of suggestion, encouragement, and confidence, in the control of symptoms.

"Patent" Medicines

THE publication of *Secret Remedies* and *More Secret Remedies* by the British Medical Association[1] some thirty-five years ago drew public attention to a public scandal. Though analyses of many worthless "patent" medicines had previously been published in these columns and elsewhere, the two books represented a declaration of war by the profession. At first success seemed certain; a Royal Commission was set up and declared itself emphatically against "cunning swindlers who exploit for their own profit the apparently invincible credulity of the public." Unhappily, its report was published on August 4, 1914, and for the next four years Parliament was otherwise occupied; but the commission's findings have remained the yardstick for the measurement of progress. That substantial progress has been made cannot be denied, though legislation still falls short, in some respects, of that recommended in 1914. Among Parliament's contributions have been the elimination, in 1917, of the treatment of venereal diseases by the unqualified; the Dangerous Drugs

Act of 1920, which stopped the sale of drugs of addiction except by a doctor's order; the Poisons Rules of 1935, which require that any preparation containing a poison must be explicitly labelled; and, perhaps most important of all, the Pharmacy and Medicines Act of 1941, which in the turmoil of the second world war slipped on to the statute-book almost unnoticed, except by the trade. Its outstanding provision is that the formula of "any article consisting of or comprising a substance recommended as a medicine" must be disclosed on the label, though unfortunately it does not insist that the substances should be called by their usual names. Other bodies too have played their part. The Pharmaceutical Society, under the Pharmacy and Poisons Act of 1933, has a disciplinary committee competent to strike from the register a pharmacist shown to have been guilty of misconduct; a considerable section of the daily press, through the Newspaper Proprietors' Association, acknowledges a self-imposed censorship of advertisements; and the Advertising Association, the Proprietary Association of Great Britain, and the Chemists' Friends Association all have agreed codes.

Is this enough? Mr. HUGH LINSTEAD, M.P., himself a pharmacist of wide administrative experience, replies emphatically No in a monograph[2] which, if it misses the incisiveness of the late Prof. A. J. CLARK's classical review of the same field,[3] is yet a balanced and scrupulously fair survey. Mr. LINSTEAD very properly explains that, despite the booklet's title, his quarrel is not with patent medicines (for with present-day law there are none) nor with the reputable proprietary preparations which most doctors are glad to use, but with the more dubious concoctions sold direct to the public—whose advertisement fosters needless fear of disease and which slim the nation's purse to the tune of £12–15 million a year. He gives a moderate but informative account of the subtleties by which this money is wheedled out of the public's pocket: he has a word for the unsolicited testimonial, the pseudo-scientific jargon and the extravagant claims of advertisements, the stimulation of false hope in the chronically sick, and, above all, the reliance on fear. On the effects of the trade he is at one with CLARK, who held that "the harm done by the frightening of individuals is much less serious than the harm that results from subjecting the public to a steady stream of misinformation regarding the elementary laws of health." Dr. THOMPSON's article on p. 280 shows how freely this stream still flows.

Mr. LINSTEAD ascribes omission to control the trade not so much to vested interest or awe of the press (which, of course, is closely affected) as to lack of public demand. The truth, he says, is that most manufacturers see to it nowadays that active ingredients are contained in their preparations, and one way or another, most of them do benefit their adherents. But he thinks that this trade fosters disease-consciousness, and leads to the postponement of seeking skilled advice, and that prices are often excessive. He suggests that the Minister of Health should be charged with over-seeing proprietary medicines; that a register of manufacturers and medicines should be kept, and that a medicine not complying with statutory conditions should be suppressed; and that advertisement and postal offers of diagnosis and treatment should be more strictly controlled, particularly to exclude false, misleading, or exaggerated claims.

Mr. LINSTEAD sees in this an element of conflict between State and individual; for he adds that "the advertising of proprietary medicine undermines public confidence in a State medical service and in the registered medical practitioners at whose hands such a service must be provided." Perhaps Mr. BEVAN also holds this view; during the committee stage of the National Health Service Bill he was heard to say that he regarded extension of the law "as a matter of some urgency."[4] The captious may reason that the warrant for further legislation was as vali years ago as it is today; but few will dispute the ne for legislation, whatever the reasoning behind i It will not be easy. What, for example, are to b the "statutory conditions" which the Minister o Health is to enforce, and how are they to be interpreted? In pharmacology the borderline betwee the active and the inert, between the therapeuti and the useless dose, is still often obscure; an if some of the conditions are to rest on such data the Minister may be denied the precise guidance h will need. But we should not be deterred by punctilio The *Economist*,[5] advocating the control of advertisements and a cost analysis, says: "If the patien does not believe the doctor when he is told that ther is nothing the matter with him, or if he does not wan to consult a doctor at all, he will be able to bu medicines that do not require a medical prescriptio at the chemist's shop. . . . But at least he will not b subjected to constant external pressure to make hi into a constipated hypochondriac." We may all accep at least this modest ambition as a first aim.

Repair of Nerve Injuries

DURING the last few years much experimental wor has thrown doubt on the view, expressed at the en of the 1914–18 war, that in the treatment of peripher nerve injuries the result is largely independent of th interval between wounding and surgical repair.[6] Th Americans, having made up their minds that delay harmful, laid their plans accordingly, and SPURLIN and WOODHALL[7] now report a series of nearly 300 early nerve operations carried out in America military hospitals in the United Kingdom, in th period roughly covered by the invasion of Europ until VE-day. In the opening phases of the ca paign the average delay before operation was 28 days in the time of heaviest fighting before VE-day i rose to 42 days, owing to the great pressure o work; and the average for the whole period wa 39 days.

Nerve suture was performed in 54% of the operations—about 1500 sutures in all—and it was foun that the operations presented relatively little difficult There was very little scarring, and the stumps were s readily mobilised that the number of gaps that coul not be closed by end-to-end suture was less than 1% The comparative absence of scarring must, of course have been attributable rather to the excellence o e primary wound treatment than to the shortness ' the time since injury. These were, however, only condary considerations, and SPURLING and WOODHALL ery properly base their advocacy of early secondary ıture on the favourable condition of the peripheral erve stump and of the denervated muscles during ıe early days after injury.[8] With the passage of me serious and ultimately irreversible changes take lace. Yet, although American and British surgeons re now convinced of the merits of early intervention, ; still remains to be decided whether early secondary uture is superior to primary. Theoretically, it is ıot; but, because of the unpredictable character of nost injuries damaging nerves, the primary operation resents certain technical hazards, the most important f which, as ZACHARY and HOLMES [9] have pointed out, s the difficulty in estimating the extent of intraıeural damage that accompanies every nerve division. Their condemnation of primary suture is shared, so ar as war injuries are concerned, by SPURLING and WOODHALL.

[7] Spurling, R. G., Woodhall, B. *Ann. Surg.* 1946, 123, 731.

A comprehensive survey of the end-results in their ases cannot be made for another two or three years, but a certain number of undoubted failures have already been recorded. Among 89 primary sutures there were 20 failures—a rate of 22%—which is distinctly higher than their figure of 5% for the series of early secondary sutures. The follow-up period had necessarily been very short: only 12 cases in one group of 649 have been examined more than a year after suture and only 201 cases have been followed for six months; so the authors have had to be content with recording only the first signs of recovery. Early indications of return of motor or sensory function were noted in slightly more than half of all cases seen six months or more after operation.

There is no doubt that the vigorous and sane policy pursued by Colonel GLEN SPURLING when he was consultant in neurosurgery in the European theatre of operations resulted in the performance of nerve suture in a very large series of cases under conditions more favourable than have ever been known before. The series of cases now reported is unique, and it is therefore all the more important that the most strenuous efforts should be made to keep in touch with all these patients. The late results may well prove the most informative in the whole history of peripheral nerve surgery.

Annotations

DANGER FROM ICE-CREAM

Now that we have learned to keep sewage and drinking-water separate, it is time to take more care over keeping fæces out of food. The control of dysentery and the enteric diseases depends on teaching people to wash their hands after defæcation. In America much more is being done than in this country to educate food-handlers about personal cleanliness, but with certain foods additional precautions are needed.

Ice-cream is like milk in that it is a perfect bacteriological medium; but, unlike milk, it does not usually start off with a legacy of pathogenic organisms. Of the substances used in its manufacture, milk, dried egg, and possibly gelatin might contain pathogenic bacteria. Regulations laid down by the Minister of Health should do much to prevent the salmonella in dried egg from causing trouble, and as some form of heat is used in the preparation of most commercial ice-cream the danger from indigenous pathogens is further reduced. In the so-called cold-mix method there are dangers, though paradoxically they may be less than in the hot-mixes, where initial heating often destroys the bacteria present in the original mixture. The chief danger in all types of ice-cream manufacture lies in human contamination, either from dirty hands or from infected droplets coughed into the mixture before it is frozen. In a recent investigation of three outbreaks of staphylococcal food-poisoning caused by ice-cream G. S. Wilson and his colleagues,[1] at Oxford, showed that in all cases the contaminated food had been allowed to stand unfrozen for anything up to 30 hours after preparation. It is during this interval between preparation and freezing that pathogens introduced into a hot-mix find not only a perfect medium for growth but almost equally perfect temperature conditions for rapid multiplication. For this reason the hot-mix method is probably the most dangerous, and the Oxford workers recommended that after preparation ice-cream mix should be frozen almost immediately if pathogens or toxin-producing organisms are to be prevented from multiplying while the mix is slowly cooling down. The remedy, therefore, is some method of immediate cooling, and we are glad to hear that the Ministry of Health is considering compulsory pasteurisation for all types of ice-cream except that made by the cold-mix method. With such regulations in force there is little doubt that large outbreaks like that at Aberystwyth could be avoided.

There remains the problem of getting some workable and reliable method for the bacteriological control of ice-cream. A total bacterial count at 37° C gives some idea of bacteriological cleanliness; but the difficulties of this test may hinder its adoption, and there is need for further study. Many local authorities are also worried because a variety of watery mixtures, sold to the public as ice-cream, may be made in insanitary kitchens, and they seem to have little power to put matters right. The outbreak at Aberystwyth may serve a useful purpose if it forces public opinion to see that such things do not happen again.

CHEMOTHERAPY IN INFLUENZA

VIRUS infections, with the possible exceptions of trachoma, lymphogranuloma inguinale, and lymphocytic chorio-meningitis, do not respond to drugs of the sulphonamide group. The influenza virus is one of those against which no chemotherapeutic agent has yet proved effective. There is ample experimental and clinical evidence that sulphonamides and penicillin do not alter the course of uncomplicated influenza; but there is equally clear evidence that these drugs have a definite place in the treatment of secondary bacterial pulmonary conditions. Disagreement about their clinical value in influenza may have arisen for several reasons. With secondary bacterial pneumonia there is no way of judging the severity of the viral infection; and if death results, this is usually attributed to incapacity of sulphonamides to cure, whereas the lethal factor may have been not bacterial but viral. Moreover, sulphonamides are not always prescribed in sufficient doses. It is by no means rare for manifestations of inflammatory lung disease to persist, after a short course of chemotherapy, into convalescence; yet when a further, and full, course is given, the infection is controlled. Apparent failure of sulphonamides can often be traced to faults of technique in their exhibition.

Detailed investigation into the mechanism of the sulphonamides in combined infections with the influenza

virus and bacteria have indicated that the severity of the viral process is unaffected by superimposed bacterial pneumonia.[1] Conversely, sulphonamides exert their antibacterial action even in the presence of a rapidly multiplying influenza virus and of extensive pulmonary exudate. This is probably because the virus, though destroying the ciliated cells of respiratory epithelium and so probably lowering resistance to bacterial invaders, does not interfere with the activity of the phagocytic cells which are important in chemotherapy. There is thus good reason for continuing to treat specifically the bacterial pneumonic complications of influenza. We may hope thereby to lower the risk of death, provided that the viral infection itself is not too severe. The white-cell count in conjunction with the clinical picture is sometimes a useful guide to the patients most likely to benefit from chemotherapy: leucopenia suggests that the infection is predominantly viral and not susceptible to this treatment, whereas a leucocytosis favours the chance of a good response.

JOURNALS OF THE BRITISH MEDICAL ASSOCIATION

We learn with regret that Dr. Gerald Horner is to retire at the end of this year from the editorial chair of the *British Medical Journal* which he has occupied with so much distinction since 1928. He will be succeeded by Dr. Hugh Clegg, the deputy editor. Meanwhile the staff of the journal has been brought up to peace-time strength by the return from the R.A.M.C. of Dr. Harvey Flack, assistant editor, and by the appointment of two new subeditors, Dr. E. G. Murphy and Dr. D. Swinscow. The responsibilities of the editor will be increased in January by the publication, under his general direction, of two important new journals, entitled *Abstracts of World Medicine* and *Abstracts of World Surgery, Obstetrics, and Gynæcology.* Brigadier G. W. M. Findlay, of the Wellcome Research Institution, will edit them, with the assistance of Dr. S. S. B. Gilder, who as prisoner-of-war in Germany acquired varied surgical experience and a knowledge of various languages.

Of the association's specialist journals the *Archives of Disease in Childhood* (which now incorporates the *British Journal of Children's Diseases*) is edited by Dr. Richard Ellis, newly elected professor of child health in the University of Edinburgh; the *Journal of Neurology, Neurosurgery, and Psychiatry* by Dr. E. A. Carmichael; and the *British Heart Journal* by Dr. Maurice Campbell and Dr. Evan Bedford—the last being published with the Cardiac Society. The *British Journal of Industrial Medicine*, with Dr. Donald Hunter as editor, is produced in conjunction with the Association of Industrial Medical Officers, and the *Annals of Rheumatic Diseases*, in charge of Dr. C. W. Buckley, with the Empire Rheumatism Council. The latest additions to the list are the *British Journal of Pharmacology and Chemotherapy*, with Prof. J. H. Gaddum, F.R.S., as chairman of the editorial committee, published quarterly with the British Pharmacological Society, and *Thorax*, edited by Mr. N. R. Barrett and Dr. J. G. Scadding, published with the Association for Study of Diseases of the Chest. The *British Journal of Social Medicine*, under the editorship of Prof. F. A. E. Crew, F.R.S., and Prof. Lancelot Hogben, F.R.S., is to come out in the New Year.

In the secretariat of the B.M.A. Dr. Charles Hill has Dr. A. Macrae and Dr. L. S. Potter as his assistants. To these have now been added Dr. E. Claxton, of Sutton Coldfield, and Lieut.-Colonel D. P. Stevenson, R.A.M.C., while Dr. Agnes Kelynack, a temporary assistant secretary since 1944, has joined the permanent staff. Dr. E. R. C. Walker has lately been appointed Scottish secretary in succession to Dr. R. W. Craig, and Mr. John Pringle, deputy editor of the *Listener*, has become press officer to the association.

TUBERCULOSIS IN THE COLONIES

Tuberculosis is now widespread among many peoples to whom it was formerly almost unknown—notably the Africans and American negroes, the West Indians, the Malayans, and the Indians. A vivid impression of its ravages is obtained from a summary compiled by Prof. S. Lyle Cummins,[1] a pioneer and life-long student of the subject. Much of the monograph is devoted to an account of work by many different investigators in Africa, but there are references to Cyprus, India, Burma, the United States, and the West Indies.

The picture which emerges is gloomy. Africans are hypersensitive to the tubercle bacillus, with so little control of infection that manual work in the gold-mines breaks down their unstable defences, and with so little resistance to overt pulmonary tuberculosis that recovery, even in the restricted sense applied in Britain, is rare. At one end of the scale of susceptibility are the Senegalese soldiers in France during the war of 1914–18, carefully observed by Borrel,[2] who were taken to an infective environment from their own country, in which tuberculosis was almost absent, and who died in great numbers of a disease they could not defeat; the form was the acute generalised tuberculosis found characteristically in European infants and susceptible laboratory animals. Those who survived were probably rather more resistant than those who died, and natural selection would therefore operate towards the breeding of a race with rather higher resistance. At the other end of the scale are the negroes of the United States, whose death-rate, though still higher than that of whites, is decreasing with the general fall. In these negroes natural selection is further advanced, and the race is relatively resistant. Between the Senegalese and the American negroes lie the mass of indigenous Africans, more susceptible than the Europeans and increasingly subject to infection. That the majority of Africans control primary infection is proved by the observation that most surviving adults are positive to tuberculin but are not diseased; but it is equally true that a far greater proportion of Africans than of Europeans fail to control primary infection, become diseased, and die.

The gravity of the position, especially in urban communities, has been recognised by the government of Tanganyika Territory, who have lately decided to extend the tuberculosis organisation directed for the past twenty years by Dr. H. N. Davies at Kibongoto.[3] It was also recognised by the medical services in the late war, as Cullinan [4] has indicated. The incidence of the disease is not, of course, determined solely by susceptibility of the community; on this basis the high rates constantly found in the Royal Navy [5] would be inexplicable. Environment, especially opportunity for close contact (as in the Navy), malnutrition (as at Belsen), and unfavourable conditions of work (as in African gold-mines), is the other obvious factor.

More knowledge is needed; but in the meantime tuberculosis is a pressing human and social problem, and the question is always, what is to be done? Inaction might in time provide a partial solution, by breeding out the susceptibles; but to accept such a measure of despair would be indefensible. Extensive social measures e required if the disease is to be checked. Opportunity r infection must be reduced by social, educational, and onomic means; malnutrition by agricultural reform and nproved distribution; and conditions of work by legis- tion and enlightenment. Of the more direct methods, nmunisation by B.C.G. or other vaccines needs early rial; the memorandum recently prepared by Prof. V. H. Tytler for the National Association for the revention of Tuberculosis[6] encourages the hope that .C.G. could be used effectively in the tropics; and the iscovery by Russian workers[7] that the vaccine may be ept for long periods in the dry frozen state may remove he major administrative disabilities of present schemes or its use.

In treatment, the standard procedures have sometimes roved disappointing in the tropics, because primitive eoples do not yet understand the importance of long- ontinued care. But this should not discourage their pplication, under the best conditions possible.

STYPTIC FROM SEAWEED

WHEN seaweed is broken in the sea the injury is healed by contact of the plant juices with the calcium ions of the water. The substance responsible is alginic acid, which is a polymer of *d*-mannuronic acid and resembles cellulose in chemical structure. Alginic acid salts are used in industry as thickening and binding agents, and fine filaments and foams can be produced; the usual source is an extract of the seaweed *Laminaria digitata*, and sodium and calcium salts are the important forms. Sodium alginate solution can be sterilised by autoclaving. When applied to raw tissue surfaces, it reacts immediately with the ionised calcium, to form a clot or layer of calcium alginate; this material acts as a styptic, and has the advantages that it is absorbable, has no deleterious action on the surrounding tissues, and, so far as is known, does not interfere with the action of drugs like penicillin; moreover, dilution with plasma does not interfere with the formation of calcium alginate. Another method is to prepare calcium alginate by adding to sodium alginate solution a soluble calcium salt to produce thin films in situ; or a foam or plastic sheet can be prepared. Calcium alginate filaments can be prepared as an absorbable hæmostatic gauze for application to oozing surfaces. Blaine, Dollar, and Sorsby[8] have described the use of calcium alginate in scleral wounds, but consider that in this site it compares unfavourably with fibrinogen. Smith[9] has reported good results with powdered alginic acid as a styptic, after tooth-extraction and other minor surgical procedures in the mouth. It is evident that these alginate products will be a useful alternative to the other absorbable hæmostatics or fixatives that have been developed during the war.

Fibrinogen is used to form fibrin films for the arrest of hæmorrhage, and it can be employed as a fixative in plastic surgery; it is, however, expensive and cannot be heat-sterilised. Oxidised cellulose gauze swells and becomes sticky when blood-soaked, and it does not depend for its action on the clotting of blood within the meshes; it is absorbable and is not invaded by fibroblasts, so that scarring is minimal.[10] Here, too, heat cannot be used for sterilisation, which is usually effected by immersion in formalin. Alginates, on the other hand, are relatively cheap, and can be sterilised by heat; gauzes of various absorption rates can be manufactured, and the starting material—sodium alginate—is stable. There is evidence that clots of calcium alginate are invaded by fibroblasts, but its action on scar tissue has not yet been described. When supplies become more plentiful, it will be interesting to see whether it can be used in hæmorrhagic diseases, such as hæmophilia, and to control oral hæmorrhage after tooth-extraction, especially since snake venoms have proved on the whole disappointing.

H. G. WELLS

A LATTER-DAY prophet, Wells increased our perception of the past, the present, and the future. Many of his ideas are now part of our mental daily life, while the central theme of his teaching has begun to sound like a platitude. He believed in education as the only hope of giving men control over themselves and hence of their own inventions. "The conviction grew continually stronger with him that man must order himself as a political animal or perish," and "every effort of his multifarious writing became consolidated upon emphasising the necessity that nations should sacrifice some part of their sovereign rights in the creation of a world State."[1] His first book was a manual of biology, and from the imaginative tales which opened so many peoples' minds to the possibilities of science he turned to novels which became more and more frankly sociological. His supreme effort in direct education was made after the first world war, when with collaborators he produced the trilogy, *The Outline of History*, *The Science of Life*, and *The Work, Wealth, and Happiness of Mankind*. His *Shape of Things to Come* was another arresting work, and was translated to millions through the cinema. As he grew old his propaganda became less effective, partly because it was more explicit; but what is more astonishing is that his spirit remained so ardent in flesh so frail. His last work, *Mind at the End of Its Tether*, refers to a familial fatty degeneration of the heart which ended the lives of his forebears and was one of the "complications" of his own "never very sound body"; he was also, one gathers, a diabetic; and in early years it was tuberculosis that diverted him from teaching to writing. The life lived apparently by a man of outstanding physical vigour and tireless energy, and extending to 79 years, was thus handicapped by at least two serious ailments.

To judge the place of Wells in the life of his time it is necessary, as the *Times* says, "to retrace the years and to recall the responses of successive generations to the intellectual challenges he hurled at them. Beyond all question he gave stimulus after stimulus to thought. The flushing torrent of his ideas left . . . few tranquil pools for the reflective reader. Yet as an urgent and genuine seeker after truth he must have persuaded multitudes to join him in his quest."[2] The interpreter of evolution was in fact a great leader of men, and his message was as important as he supposed.

Dr. OTTO MAY, chairman of the British Social Hygiene Council, and until his retirement principal medical officer of the Prudential Assurance Company, died on August 15 at the age of 67.

TRAFFIC IN DANGEROUS DRUGS.—The Advisory Committee on Traffic in Opium and other Dangerous Drugs has resumed the issue of summaries of illicit transactions and seizures of narcotics, which has been delayed during the war years. The summaries for the years 1942–45 deal with seizures of raw opium, prepared opium, morphine, heroin, cocaine, and indian hemp, and cover Europe, Asia, Africa, America, and Australia. The report bears testimony to vigilance on behalf of world-wide administrations in tracking out centres of illicit manufacture and exposing clandestine traffic in habit-forming drugs. It is interesting to note that indian hemp, in the form of hashish, was seized in considerable quantities in Egypt, and in the form of marihuana cigarettes in North and South America, while Palestine also was not immune from illicit traffic. In 1942 4689 kg. of hashish in all were seized in addition to marihuana, as such, and in cigars and cigarettes.

Special Articles

ADVERTISING PATENT MEDICINES

J. W. P. THOMPSON
M.B. Camb., D.P.H.
DEPUTY COUNTY MEDICAL OFFICER, DORSET

THE *medical profession has not* been backward in calling attention to the obvious barriers which prevent large numbers of people from attaining full health, but there are less conspicuous obstructions which deserve more attention than they have received. One of these is the false learning unavoidably imbibed by the public from patent-medicine advertisements.

For many years past considerable concern has been expressed about the methods adopted by the manufacturers of patent medicines to sell their wares, and about the gullibility of the public who repay the manufacturers so handsomely for their expenditure on propaganda. An estimate of the extent to which the public drug themselves with advertised products was published by Davies (1944). My object here is to provide further ammunition for those who wish to draw attention to the less desirable aspects of this trade. It should be clear from the start that what is criticised is not the patent medicines, however much some of them may deserve criticism, but the advertisements which tend to give the public so many misleading ideas.

The scope of the present investigation was not large. It consisted merely in an analysis in detail of the advertisements appearing in two consecutive issues of a weekly provincial newspaper. About 40% of its space is taken up by news and 60% by advertisements, including the usual small advertisement section and the advertisements officially sponsored by Government departments.

The space taken by patent-medicine advertisements was 10% of the total printed matter, or a quarter of the space given to news. Excluding the space taken by Government departments, 25% of the total advertising space was taken by advertisements of patent medicines and ointments. The advertisements of ointments, though less numerous, are often as misleading as the advertisements of patent medicines. They will not be referred to again, as they were not included in this investigation.

The patent-medicine space was about equal to the total space taken by seven separate Government departments, and ten times greater than the space taken by the Ministry of Food—the only department offering useful advice to the public on subjects related to health. No space was taken by the Ministry of Health.

ANALYSIS OF ADVERTISEMENTS

In all, twenty patent medicines were advertised. Eight of these were given space in both issues of the paper, making a total of twenty-eight separate advertisements. The indications for self-medication given in these advertisements numbered 69, which gives an average of between 3 and 4 indications per product. The average does not give a *true* picture, as one manufacturer lists 21 indications for his medicine (a laxative), and another, more ethical, prints no indications for his salts, but states unequivocally that they are necessary for health. The variety in the number of indications for the various products was as follows :—

Products	*No. of indications*	*Products*	*No. of indications*
1	0	2	7
3	1	2	9
4	2	2	10
1	3	1	19
1	4	1	21
2	5		

Of the products which rely on 1 indication only, claim is made for the first to cure obesity, the second constipation, and the third *limping*. It is not surprising that the third is described as a wonder tablet. Of the 69 indications, 40 appeared only once, 16 twice, 4 three times, 5 four times, 2 five times, and 1 six times. Needless to say, the indication which appeared six times was constipation. Bracketed for second place in popularity came headaches and joint pains. Indigestion, muscular pains, rheumatic pains, and lumbago shared third place, while backache, neuralgia, and acidity came in fourth. It is impracticable to mention all the also-rans, but among the more outstanding were gasping, choking, intestinal ulceration and fermentation (apparently regarded as equally serious), asthma, nerviness, dizziness, depression, sleeplessness, blurred vision, bloodshot eyes, pimples, stomach pain, morning sickness, colds, influenza, hay fever, sciatica, gout, irritability, urinary troubles, bladder troubles, gravel, fretfulness, boils, cramp, eczema, rashes, ulcers, and varicose legs.

Pain of one sort or another is mentioned forty times in these advertisements, whereas the varieties of symptoms which may be grouped under the term "indigestion" obtain only twenty-two mentions. *A further* eight indications cover intestinal complaints *other than* indigestion—from bad breath to piles.

Of *the* 20 *medicines advertised*, 9 are laxatives, 4 analgesics, 3 anti-indigestion remedies, and the remaining 4 are for coughs, kidneys, blood impurities, and vascular disorders.

I have classified the advertisements into four groups :—

	Products
(1) Dangerously misleading in at least one respect ..	5
(2) Misleading, and possibly harmful	8
(3) Not definitely misleading, but excessively optimistic	2
(4) Probably useful for the purpose indicated ..	5

Of the 13 products in groups (1) and (2) 5 are laxatives, 2 analgesics, 2 anti-indigestion medicines, 1 a cough medicine, 1 a blood tonic, 1 a medicine for the kidneys, and 1 a medicine for vascular disorders.

Advertisements in Group (1).—It surely cannot be considered other than dangerously *misleading to* inform the public that the fight against asthma can be won with one sure blow, and that normal breathing returns and *distress vanishes after taking a particular nostrum*. It is equally misleading to claim that an analgesic can *banish influenza overnight, and that it* strikes deep at the underlying causes of pain and illness. It is certainly far from advisable for the public to put their faith in tablets which are said to strengthen and flush out the kidneys and should on that account be used for urinary and bladder troubles, gravel, and scanty or too frequent urine. Finally, I have included in this group those advertisements which claim that *intestinal* ulceration can be cured or alleviated by the products concerned. One of the advertisers in this group emphasises that his preparation, which is described as a modern remedy, is available to all without prescription, thereby implying that the advice of a doctor for a serious complaint not necessary.

Advertisements in Group (2).—*The following* exhortations occur in the 8 advertisements I have included in group (2) :—

"Beat indigestion anytime and everytime it strikes . . . with fifteen indigestion-taming ingredients."

"Throw poisons out of the system . . . generous formula deals with all the ills that put people off the job."

"*Look to your nerves*" (a nerve-building medicine recommended for neuritis).

"*Slim while you sleep.*"

"Remove blood impurities—root cause of blood and skin complaints."

"*Cool* and cleanse the blood-stream from teething-time to fourteen years."

"Stop limping."

"Wake up your liver bile."

EXTENT OF SELF-MEDICATION

A study of the advertisements gives no indication of the extent to which the public buy and use these products. In his inquiry in Bristol Davies (1944) discovered that practically 75% of the persons questioned were taking medicines other than under medical advice. Those taking laxatives and those taking analgesics were about equal. This is not out of line with the relative amount of advertising space taken by these two types of product, as, though more laxatives are advertised, the analgesics are, on the whole, given more forceful copy. What is surprising is that comparatively few of the persons questioned in Bristol were taking anti-indigestion medicines, which have nearly as much advertising space as the analgesics and are given equally forceful boosts. It is not so surprising that few "preventives" (vitamins, iron, &c.) were being taken, as these potentially useful preparations get very little advertising space compared with the three big groups of patent medicines.

COST OF PATENT-MEDICINE ADVERTISEMENTS

In 1938 the estimated cost of advertising patent medicines in the press was £3,692,856 (Bishop 1944). This figure is 11% of the total cost of all newspaper advertisements. It is greater than the amount spent on any other individual group of products, except foodstuffs, which exceed it by a mere £200,000. By far the largest proportion of the expenditure on advertising foodstuffs was in connexion with health and baby foods, some of which are advertised as though they were patent medicines. The amount spent on advertising alcoholic drinks was only a third of that spent on patent medicines, and on cigarettes less than half.

Analysis of the expenditure on patent-medicine advertisements shows that laxatives lead the field with £650,000. Indigestion remedies cost £370,000, and aspirin and pain-cures £360,000.

Expressed as a percentage of total retail sales, the advertising cost of the group of products in which patent medicines are placed was 34%—by far the most expensive advertising. The figure for foodstuffs was 0·86%. A comparison of advertising and production costs for patent medicines does not appear to be available. It might be interesting if it were.

In 1938 the total sum spent on dispensing National Health Insurance prescriptions and appliances was £2,660,850—i.e., two-thirds of the sum spent on advertising patent medicines.

CONTROL OF PATENT-MEDICINE ADVERTISEMENTS

Under the Venereal Disease Act, 1917, the advertising of medicines for the treatment of venereal diseases is prohibited. The Cancer Act, 1939, prohibits the advertising of medicines for cancer. Under the Pharmacy and Medicines Act, 1941, advertisements of remedies for the following diseases are prohibited: Bright's disease, cataract, diabetes, epilepsy or fits, glaucoma, locomotor ataxy, paralysis, and tuberculosis. The advertising of abortifacients is also prohibited under this Act.

Section 6 of the Food and Drugs Act, 1938, lays down that a person who publishes an advertisement which falsely describes any drug, or is otherwise calculated to mislead as to its nature, substance, or quality, shall be guilty of an offence. Under the Defence (Sale of Food) Regulations, 1943, it is also an offence to publish an advertisement which misleads as to the nutritional or dietary value of a food; and, according to the Food and Drugs Act, 1938, an article shall not be deemed not to be a food by reason only that it can also be used as a medicine.

Many manufacturers of patent medicines are members of the Proprietary Association of Great Britain, which has issued a code of rules for advertising. One of the objects of the rules is to ensure that advertisements are of such a character that they do not mislead the public or contain statements which would permit criticisms to be levelled at proprietary medicines as a whole, or which may cause public confidence in proprietary medicines to be impaired (Chapman 1942). This code of rules was in force for some years before the passing of the Pharmacy and Medicines Act, 1941, and in some respects the rules are in advance of the law. It would be interesting to know which manufacturers are members of the association, so that their advertisements could be compared with those of the non-members.

The Ministry of Food, in consultation with the Medical Research Council, has drawn up for food manufacturers a suggested code of practice in framing labels and advertisements. Among other recommendations the following advice is given about claims connected with the vitamin or mineral content of a food: "Unless the amount of the food that would ordinarily be consumed in one day contains at least one full daily requirement of the vitamin or mineral, no reference is justified to the value of the food for the prevention or cure of disease due to the lack of the vitamin or mineral present in the food."

As a further check on the publication of misleading advertisements, the Newspaper Proprietors' Association adopted certain rules about the acceptance of proprietary-medicine advertisements by newspapers represented in the N.P.A. (*British Medical Journal* 1943). The rules appear to be closely related to the Proprietary Association's code. Possibly not all newspapers are bound by these rules. Certainly misleading advertisements continue to appear.

DISCUSSION

In this country the sale of drugs and medicines of all kinds has been an open trade. It is only since 1868 that the sale of poisons has been controlled. The advertising and sale of patent medicines were the subject of inquiry by a select committee in 1912. The concluding paragraph of their report was as follows:—

> "For all practical purposes British law is powerless to prevent any person from procuring any drugs or making any mixture, whether patent or without any therapeutical activity whatever (so long as it does not contain a scheduled poison), advertising it in any decent terms as a cure for any disease or ailment, recommending it by bogus testimonials and the invented opinions and facsimile signatures of fictitious physicians, and selling it under any name he chooses—on the payment of a small stamp duty—for any prices he can persuade a credulous public to pay."

The law has been strengthened since then, but it is not nearly so effective as it might have been, had Dr. Addison's Proprietary Medicines Bill not been withdrawn from Parliament in 1920. In this Bill provision was made for the establishment of a register of proprietary medicines, and the sale of unregistered medicines was to be prohibited. The Minister of Health was to have been empowered to remove from the register any injurious medicine or appliance.

Possibly another attempt should be made to strengthen the law regarding the manufacture and sale of patent medicines, as it is perhaps over-optimistic to expect that good sense and good taste will eventually prevail over prejudice and ignorance. In so far as the control of misleading advertisements is concerned, it seems that section 6 of the Food and Drugs Act, 1938, gives power to take effective action, though the legal difficulties in the way of bringing a prosecution to a successful conclusion would be formidable.

In some other countries the interests of public health take precedence in cases where they may be in conflict with commercial speculation. The Proprietary or Patent Medicine Act of Canada states:—

> "No proprietary or patent medicine shall be manufactured, imported, exposed, or offered for sale or sold in Canada if the

article be represented as a cure for any disease, or if any false, misleading, or exaggerated claims be made on the wrapper or label, or in any advertisement of the article."

This country is peculiar in that there is a widely held belief that a bottle of medicine is something no healthy person should be without. This trust in medicines is not a new thing. Oliver Goldsmith wrote :—

> "The English are peculiarly excellent in the art of healing. There is scarcely a disorder against which they are not possessed of an infallible antidote. The advertising professors here delight in cases of difficulty. You will find numbers in every street, who, by levelling a pill at the part affected, promise a certain cure."

Though it must be agreed that the cost of persuading members of the public to buy patent medicines is out of all proportion to the good these preparations may do, the point of view put forward by Bishop (1944) would probably obtain considerable popular support :

> "The consumer may not always appear to choose very wisely, but perhaps he would prefer to risk mistakes and occasional deception in the exercise of his own free choice rather than submit in the matter of his daily purchases to the judgment of some central authority, however wise and benevolent."

There is no getting over the fact, however, that the wording of some advertisements is deliberately misleading. This would not matter much if the public were reasonably well informed, but unfortunately the public appear to be both gullible and ignorant. The defence of an advertising expert is worth quoting in full :—

> "People are very rarely misled by advertisements except when they wish to be misled. And few advertisements, in spite of all appearances to the contrary, are really intended to mislead. There is a robust and saving common sense, and a humour and proportion about the ordinary consumer which are better understood by those who seek his custom than by those who are so anxious to protect him against himself. Of course freedom is dangerous, and free competitive advertising is strong meat, not always easily digestible by delicate stomachs. For that reason it is rightly to be regarded with caution, and used with a sense of responsibility. But freedom to persuade, in economic as in religious or political matters, is the right food for a free society. Its benefits certainly cannot be measured in pounds, shillings, and pence." (Bishop 1944.)

It may be the view of some that newspaper advertisements are harmless because few if any people bother to read them. Those who doubt the power and influence of advertising perhaps do not realise the extent to which manufacturers rely on advertisements to increase sales. Messrs. J. Lyons and Co. Ltd. have revealed that, before they started advertising their swiss rolls on a big scale, they were selling 10,000 a week. Shortly after advertising began the sales rose to 600,000 a week.

Short of a compulsory censorship of advertisements—a procedure which should be unnecessary in any country where the public is well informed—what can be done to counteract the harmful advertisements? These presumably take the form they do because the manufacturers are unable to agree that their advertisements should be consistent with modern pharmacological and medical knowledge—admittedly this might lead to a great loss of trade—and because newspaper proprietors do not always insist on every patent-medicine advertisement being scrutinised by a reputable medical authority.

Perhaps the most promising lines of attack would be (1) for general practitioners to talk over with their patients the question of self-medication with patent medicines; and (2) for some public body to insert health advertisements in the newspapers as a direct counterblast to the patent-medicine manufacturer. Possibly the advertising space now taken to enlighten the public about venereal disease might with advantage be used occasionally for a short homily on the treatment of constipation. By these means the public might gradually be weaned from their belief that most patent medicines are a kind of cocktail for making life tolerable in these times.

SUMMARY

The advertisements of patent medicines appearing in two consecutive issues of a weekly provincial newspaper are analysed.

The cost of patent-medicine advertisements and the control at present exercised over such advertising are discussed.

The conclusion is reached that many advertisements are misleading, and suggestions are made for counteracting the harm done by them.

MUNICIPAL SPECIALIST SERVICE

THE BRISTOL SCHEME

IN 1938 the Bristol city council adopted a new policy for the employment of specialists at their hospitals and health centres. Till then specialists had been engaged for specific duties and paid on a sessional basis or by honorarium based on the usual sessional rate of payment. Under the new scheme surgeons, physicians, and obstetricians and gynæcologists have worked as teams under the directorship of the university professor of their group. Three or four teams were organised in each group, and a sum of money was paid to the professor for distribution between the members of his teams according to services rendered. One of the conditions was that the teams should meet regularly as a committee at the municipal hospital and make suggestions for the improvement and development of the services, and the many useful recommendations made at these meetings have been appreciated by the administrative staff of the public-health department.

This scheme, which has many advantages, has worked well in spite of the war, which reduced the number of consultants and increased their work. But now the expansion of the service is demanded by the needs of a comprehensive school medical service, of health centres, and of an E.M.S. hospital recently taken over by the city. At the same time the university has had to reorganise its medical teaching so as to train more specialists, and this will decrease the number of teaching staff available for treatment of patients, while the professors of the medical faculty will be less able to take part in the supervision of corporation services.

A joint advisory committee, on which the city council, the university, and voluntary hospitals were represented, was therefore constituted to consider appointments to hospitals and health-centre staffs. The medical faculty of the Royal Hospital suggested certain general principles for the organisation of the specialist services in the city hospitals, voluntary and municipal, which the joint committee accepted in the following form :

(*a*) The consultants and other medical personnel should be organised into units to which the work would be allocated.

(*b*) Each unit should be the clinical team, which normally should consist of two members of the visiting staff (preferably a senior and a junior), a registrar, and a house-officer, with or without clinical assistants.

(*c*) Where the work of a department or specialty is greater than can be dealt with by one unit, and a second unit is created, each unit should be equal in status.

(*d*) University professors and heads of departments should be in general charge of teaching, but each team should be entirely responsible for its clinical work.

(*e*) Registrars should be appointed as members of a team and not to a department.

(*f*) Outpatient consulting sessions should be held at the Royal Hospital by all the teams. The members of all teams should be on the Royal Hospital medical staff, irrespective of whether they have beds in the hospital.

(*g*) The beds allocated to a team should be, as far as possible, in one hospital.

Last month the city council approved a report based on these principles for the staffing of its municipal hospitals and health centres. The cost of specialist services to the corporation when this scheme comes into full operation will be £22,000 per annum—a yearly increase of about £11,000.

HOMŒOPATHY AND THE BILL

Mr. Aneurin Bevan, the Minister of Health, with Dr. J. A. Charles and Mr. J. M. K. Hawton received a deputation on June 27 from the British Homœopathic Association, which included Dr. Alva Benjamin, Sir John Weir, M.B., and Dr. W. Lees Templeton. The deputation said that many people in all parts of the country wished to have homœopathic treatment, which should therefore be provided for them under the National Health Service. To ensure that this demand was adequately met they asked that certain homœopathic hospitals should be designated as teaching hospitals under the Bill, and that the homœopathic doctor should not be debarred from practice in an area on the grounds that there was already a sufficiency of non-homœopathic doctors.

In reply, Mr. Bevan said he hoped that the homœopathic hospitals, in general, would come into the National Health Service scheme, and he would try to preserve their special character and atmosphere, like that of other special types of hospital, by making suitable appointments to the management committees, &c. He thought, however, that the regional hospital boards would have to look at the services in any given area before a conclusion could be arrived at about any particular hospital. He could not give any assurance as regards designating homœopathic hospitals as teaching hospitals; it was not his function to determine what kind of training was to be given in teaching hospitals, and the university authorities must come into this question. There would be no discrimination against homœopathic methods of practice; equally, of course, there would be no discrimination in favour of them, or of any other particular clinical methods.

Many of these problems, the Minister added, might ot prove so formidable in practice as they might seem ı theory, and he would gladly ask the association to eet him again at a later stage when the preparations ere being made to bring the Act into operation.

On Active Service

AWARDS

The following awards have been made in recognition f gallant and distinguished services in the Far East:

C.B.E.

Brigadier C. H. Stringer, D.S.O., O.B.E., L.R.C.P.I., late R.A.M.C.

O.B.E.

Lieut.-Colonel D. C. Chopra, M.B., I.M.S. (since died).

M.B.E.

Major S. M. Banfill, R.C.A.M.C.
Major J. N. B. Crawford, R.C.A.M.C.
Major C. W. Maisey, M.R.C.S., R.A.M.C.
Major J. A. G. Reid, R.C.A.M.C.

MENTIONED IN DESPATCHES

COMMANDS AND STAFF

Colonels.—E. Percival, D.S.O., M.C., late R.A.M.C.; V. H. Wardle, M.C., late R.A.M.C.

R.A.M.C.

Brigadier D. S. Middleton.
Colonels.—J. Bennet, J. Taylor, O.B.E.
Lieut.-Colonels.—J. W. Craven, M.C., W. G. Harvey.
Majors.—H. M. S. G. Beadnell, M.B.E., P. R. Graves, M.B.E., H. Henderson.
Captains.—J. E. A. Bartlett, M. H. Churchill, T. R. S. Cormack, E. K. Cruickshank, J. G. Jesson, W. H. McDonald, J. A. Mark, T. B. Smiley, M.C., R. B. C. Welsh.

R.C.A.M.C.

Major G. C. Gray.

The President of the United States has conferred the degree of officer in the Legion of Merit on Major-General Sir Edward Phillips, K.B.E., C.B., D.S.O., M.C., M.B., late R.A.M.C., and the bronze star medal on Colonel Thomas Parr, M.D., R.A.M.C.

In England Now

A Running Commentary by Peripatetic Correspondents

You will remember King Aethelbeorht (the vulgar call him Ethelbert), who married Bertha, and received St. Augustine under an oak tree, and became the first Christian king of England. Well, they had Laws even in those days, and I want to call the attention of Mr. Paling, Minister of Pensions, to their excellence. For example, Aethelbeorht says that "if the eye and foot of a servant are destroyed by wounds his full value shall be paid." The Ministry, allowing for the difference of outlook in so many hundred years, says much the same thing, but you have to lose the eye and a leg above the knee to be sure of 100%. Of course, the comparison between Aethelbeorht and Mr. Paling is not perfect. Aethelbeorht is talking about single payments in cash or cows while Mr. Paling is concerned with weekly payments. But we can make some sort of comparison. Here are some of the things for which compensation of 12*s.* was due in A.D. 600—if an ear is struck off, if the power of speech is injured, if the belly is wounded, if the thigh is broken. That was Aethelbeorht's code. Now look at Mr. Paling's. Loss of an ear 7% only, but complete loss of speech would probably be 100%, and abdominal wounds and thigh fractures would be judged upon the amount of disablement produced. The comparison is in favour of Mr. Paling, and Aethelbeorht appears rather stolid and unimaginative.

On the other hand his Laws did, in other directions, imagine ways of incurring a 12*s.* compensation which would shock Mr. Paling's department. Thus 12*s.* was the proper compensation payable (I expect the King and his relatives shared it) for excessive attachment to a widow, that is, if she was of the third class: a second-class widow cost the offender 20*s.* If the lady was married, and her husband alive, the freeman involved must buy the wife from her husband, and then provide him with a new wife at whatever it might cost him. This seems rather hard upon the husband who was thus deprived of the sanctions of the unwritten law. He might not indulge in physical retaliation, for "if one man strikes another on the nose with his fist" 3*s.* compensation was payable, and if the hæmorrhagic nose was carried to a doctor for treatment a further 30*s.* had to be paid. This argues that the medical treatment of Aethelbeorht's day was not to be lightly borne or, perhaps, that the doctors were so skilled that they were worth a fee of what, in modern money, would certainly be at least £50.

Mr. Bevan ought to be told about this. He is a Progressive (or a backslider, everything depends upon the point of view) and now he is offering a paltry 12*s.* 6*d.* for a whole year's treatment while Aethelbeorht lays it down that we ought to have £50 for treating an epistatic nose, or ought it to be "epistasic"? It is true that Aethelbeorht was a mere Anglo-Saxon, while Mr. Bevan is an obvious Celt, but even Celtic doctors were better paid than we are going to be. For example, for treating a bishop the Celtic doctor could expect a fee of 40 cows, and even a slave was worth 2 cows, or the equivalent in sheep or goats. There are no slaves here nowadays and every man is as good as a bishop, or better. It is abundantly evident that we ought to have at least a capitation fee of 40 cows, according to the Brehon code, which was probably just as much Welsh as Irish, although St. Patrick seems to be mixed up with it somehow. So let us face this upstart Welshman with cries of "back to Aethelbeorht" and "give us our cows."

* * *

Like me, they had obviously come over to Yarmouth for the day. It was late afternoon, and Father, Mother, and Auntie had had enough of it. Three-year-old Binkie, weary and fractious, was lagging behind. Mother turned and spoke sharply to him—"Binkie, if you don't something-or-other I shall something-else; you see if I don't." With the time-stopping sensation of *déjà vu* I knew exactly what was going to happen next: and it did. Binkie tottered forward wildly to catch up, tripped, fell, and lay prone, bellowing to high heaven for comfort and sympathy. Mother, torn between conflicting emotions, jerked him up, petted him, dusted his clothes roughly, wiped his face gently, chid him, and gave him to Father to carry.

intense headache and backache, and all other prodromal symptoms may be present, including erythematous or petechial eruptions . . . its true nature is shown by its occurrence in an epidemic focus and by the sudden termination of the disease on the third day before the appearance of the papular eruption. Such cases are apt to be encountered among recently vaccinated persons shortly after joining the staff of a smallpox hospital, and several examples have lately been reported among recently vaccinated soldiers (Vorpahl, Klaholt, Kathe)."

Harries and Mitman (1940) describe variola sine eruptione as " smallpox confined to the initial toxæmia occurs in the previously vaccinated. . . . Occasionally a few small and atypical focal lesions may appear and be possibly overlooked."

In view of the so-called abortive case in this outbreak and the extracts quoted above, it seems reasonable to conclude that such cases may show some or all of the prodromal signs and symptoms of smallpox, and that these then fade out without any appearance of the true rash. We suggest that abortive smallpox would be a better and simpler name for the conditions previously described as variola sine eruptione, variola sine variolis, and contact disease.

VACCINATION OF CONTACTS

The present outbreak led to a considerable demand for vaccination. The contacts of H. R. were numerous, and many of them unknown; and A. R., during the first three days of his illness, had attended church services, a Sunday school, a wedding, and a technical school. Vaccination was offered to all known contacts, and a special vaccination session for children was held in the technical school. The public vaccinators were hard pressed, because, besides ordinary contacts, all laundries, libraries, and salvage-collecting personnel were warned. By Feb. 23 the list of known contacts exceeded 1000, and assistance was given by the county medical and nursing staffs.

On March 3 it was decided to open special vaccination centres. Up to this time all contacts had been vaccinated at the public vaccinators' surgeries (except the special clinic held for school-children). By March 9 five centres had been opened. These were greatly appreciated, as the weather had been particularly bad and there had been long queues standing in rain and snow outside the doctors' surgeries. In the five days March 4–9, 15,000 vaccinations were performed in the district. The assistance given by the Government Lymph Establishment at Colindale Avenue, London, N.W.9, was greatly appreciated.

On the whole, everything worked well, yet experience showed where improvements might have been possible. After the first few days it was realised that it would not be possible to reinspect all vaccinated contacts; so the public were informed that the only people who would be seen again a week after their vaccinations were (1) those who had been vaccinated for the first time and whose vaccination had not taken; (2) all infants under the age of one year (for vaccination certificates); and (3) all persons vaccinated by private doctors. The vaccinators by this time consisted of public vaccinators, other practitioners, medical officers on the staffs of health departments, and medical students working under supervision. It was necessary for private doctors' patients to be seen again so that records for payment, &c., might be completed. Some improvement might have resulted from giving known contacts a document that would have given them priority in the queues.

All contacts were vaccinated in three places, and members of the general public in only one. Meanwhile the sanitary inspector's staff had been reinforced, and all contacts were visited daily for seventeen days. Any found to be ailing, however slightly, were transferred to a special contact list and visited daily by a medical officer, and returned to the original list when a negative diagnosis had been made.

As indefinite rashes from vaccination, smallpox, o for some other reason might arise, a ward of 12 be was held in readiness at the local isolation hospital f the reception of any such cases. Three cases we admitted, and the provision of this ward proved to be definite safeguard.

A single large room, free of unnecessary furniture, w found to be the ideal vaccination centre, with, if possib additional shelter for applicants. The queue should be divided into smaller queues according to the numb of vaccination teams. Each vaccinating team shoul consist of a clerical assistant (to whom the patient go first) to enter particulars on the form, a nurse to prepar arms, the medical officer, and a volunteer to cover th vaccination mark with strapping after drying.

CONCLUSIONS

The following conclusions may be drawn from t experience:

(1) It is desirable that persons in attendance o smallpox patients on board ship should be specifical notified to the medical officers of health of the di to which they proceed when they land in this count

(2) Vaccination in infancy may protect for very man years, but does not necessarily do so.

(3) It appears likely that one vaccination mark do not protect as completely as two or more. It seem desirable that a primary vaccination should consist three marks, and a revaccination of at least two.

(4) During an outbreak, when there is a rush vaccination centres, contacts should be given priori by a system of tickets.

(5) For doubtful rashes an observation ward in t nearest isolation hospital is of great value.

(6) Abortive smallpox would be a good name for t illness now known as variola sine variolis, variola si eruptione, or contact disease.

Our thanks are due to Dr. T. Stevenson Logan, M.O.H. Southend, for the information concerning the Southend ca

Detection of Typhoid Carriers

THE monthly bulletin of the Ministry of Health a the Emergency Public Health Laboratory Service f November contained a note on the detection of typh carriers, and practitioners may like to be reminded the suggestions made:

> "A chronic carrier may cease to excrete typhoid bac for no apparent reason, and may resume doing so witho any detectable alteration in his well-being. Epidemiologi evidence, although not conclusive, suggests that the interv of freedom may last for months or even years, but the agglutination test remains positive during these interv It is not proposed that any control, other than that affor by the Public Health (Infectious Diseases) Regulations, 1 should be exercised over carriers, and in this connexion t attention of medical officers of health is called to pages to 60 of the Annual Report for 1932 of the Chief Medi Officer of the Ministry where the subject is dealt with.
>
> "The method of detection is, before discharge from h pitals every typhoid convalescent should have a blood t for Vi-agglutinins. If they are absent, no further action ne be taken. If present (as might be expected in about one-h the cases) a second test should be made three months la when, if they are no longer present, nothing further need done. If, however, Vi-agglutinins are present in a titre high as, or higher than, before, two examinations a we for three weeks, of the stools and urine or, failing this, examinations with as long an interval as possible between should be made by selective cultural methods to find whether typhoid bacilli are being excreted. If they are, t patient should be regarded as a persistent carrier; if th are not, it might be advisable to repeat the Vi-agglutinati

three months later to see whether the titre is falling. her action would depend on circumstances.

As every case of typhoid fever owes its origin to a carrier dder), it is an obvious advantage to a medical officer of th to know at least some of the potential sources of tion in his district. By ascertaining the type of infecting nism by the Vi-bacteriophage method, and by keeping a ster of the names and addresses of the carriers thus typed, nay prove easier to trace the source of infection of fresh s when they arise.

The Emergency Public Health Laboratories have been uested to do all they can to assist medical officers of health naking the proposals effective."

t is estimated that in 5% of cases of typhoid fever aised titre of Vi-agglutinins persists for six months or re and that 2% or more of patients become chronic riers. Of the latter, 90% have a permanently elevated agglutinin titre. The measurement of Vi-antibody is erefore a valuable indication of the carrier state.

Typhoid and Paratyphoid

Up to August 19 123 cases of typhoid had been mitted to hospitals in Wales and 2 had died. Further ses in visitors believed to have been infected by means ice-cream consumed at Aberystwyth have been admitted hospitals in various parts of England but the total mber is uncertain. This outbreak appears to be on e decline, as might be expected following the discovery the vehicle of infection.

A number of persons, mainly children, living in Halifax nd surrounding districts are suffering from an illness elieved to be paratyphoid B and have been admitted hospital. The nature of the illness and its origin are eing investigated.

Infectious Disease in England and Wales

WEEK ENDED AUGUST 10

Notifications.—Smallpox, 0; scarlet fever, 707; whooping-cough, 1910; diphtheria, 243; paratyphoid, 13; typhoid, 89 (48 in Cardiganshire); measles (excluding rubella), 3299; pneumonia (primary or influenzal), 298; cerebrospinal fever, 34; poliomyelitis, 18; polio-encephalitis, 1; encephalitis lethargica, 1; dysentery, 84; puerperal pyrexia, 149; ophthalmia neonatorum, 58. No case of cholera, plague, or typhus was notified during the week.

The number of service and civilian sick in the Infectious Hospitals of the London County Council on August 7 was 900. During the previous week the following cases were admitted: scarlet fever, 36; diphtheria, 28; measles, 61; whooping-cough, 31.

Deaths.—In 126 great towns there were no deaths from enteric fever or scarlet fever, 2 (0) from measles, 7 (0) from whooping-cough, 2 (0) from diphtheria, 34 (5) from diarrhœa and enteritis under two years, and 3 (0) from influenza. The figures in parentheses are those for London itself.

The number of stillbirths notified during the week was 61 (corresponding to a rate of 32 per thousand total births), including 28 in London.

A LIBRARY BAEDEKER.—The National Research Council of America has brought out under the editorship of Mr. R. R. Hawkins, chief of the science and technology division of the New York Public Library, a *list of Scientific, Medical, and Technical Books*, published in the United States from 1930 to 1944 which are still in print and available for domestic and foreign distribution. The task of deciding which books were to be included was undertaken by a committee of the council under the chairmanship of Mr. Harrison Craver and, after his retirement through illness, of Dr. John Fulton. The committee believed that a carefully selected group of books would be more useful than a longer but less informative list, and the complete title, publisher, price, and list of contents of each of the 6000 books included is given, accompanied by a short descriptive commentary on the book's purpose and scope. As a guide to the jungle of present-day technical publications the list will be of value both to the expert and to the casual inquirer, and is one more proof that Americans realise it is important that books should be read as well as written. Inquiries about the bibliography should be addressed to the United States International Book Association, 27, East 67th Street, New York City, 21.

Letters to the Editor

PROSPECTS IN POLIOMYELITIS

SIR,—We have read with dismay your leader of July 27 in which it is implied that the efforts to control poliomyelitis in Ireland are "applied on a large scale without more justification than that of the placebo." May we draw attention to points in your leader which are open to criticism and correction?

(1) The scheme of control did not (as stated in your leader) include chlorination of water-supplies, but recommended the boiling of milk and water in all areas where a piped supply was not available. In only one case was chlorination of a water-supply advocated—namely, in the case of a large boarding-school whose supply came from a private reservoir. For this school also the immersion before washing of all feeding utensils in *heavily chlorinated water* was advised. This is a procedure very different from the chlorination of water-supplies to rid them of bacterial pollution. It was a more sensible and practicable measure to advise than the boiling of all crockery, knives, and forks, which for many reasons would not have been possible.

(2) You state that the committee of experts who advised on poliomyelitis in boarding-schools was guarded in its advice on quarantine. This is not correct. In (*a*) the note to headmasters, (*b*) a suggested "form of letter" to parents, and (*c*) the revised section on poliomyelitis in the *Code of Rules for the Prevention of Communicable Diseases in Schools* (*Lancet*, 1946, i, 972) quarantine for three weeks is definitely recommended.

(3) You suggest that the difficulties rendered quarantine impracticable, and that there is "no solution to the problem of compensation for loss of earnings which at once arises when a quarantine of adult contacts is attempted in the ordinary household." In this country, under the Public Health (Infectious Diseases) Regulations 1941, local authorities compensate for any damage sustained by persons who are affected by public-health measures taken to control the spread of infection; for instance, compensation has been paid to farmers prohibited from sending milk to creameries. The economy of rural Ireland, where towns are small and scattered and the vast majority of the population lives on separate small holdings, permits of a high degree of quarantine. It was precisely to show the practicability of this procedure in Ireland that we wrote the paper which you published on July 6.

(4) You question the value of school closure. Since F. M. Burnet was mentioned in your leader, may we refer to the fact that in the Melbourne epidemic of 1937–38 he found (Dunham lectures, Harvard, 1944) that some fairly direct chain of contact between children could nearly always be traced. Geographical spread of the disease from suburb to suburb was very evident, and in nearly every instance the first child to be infected in a new suburb could be shown to have visited, or been visited by, a child from a suburb already affected. There was no evidence of carriage of infection by adults. Poliomyelitis in the Melbourne epidemic, he believed, was spread from child to child as a result of their own contacts—the source of the virus being sometimes salivary, from pharyngeal infection, and sometimes fæcal.

In rural Ireland the school is the principal point of child aggregation. Neglect of such an important means of transmission cannot be entertained.

(5) You say that "the relation between flies infected by excreta or sewage and the spread of the disease among human beings has not yet been established." This statement must be accepted with reserve, since it has not yet been proved that there is no relation, and particularly since (in point of time, &c.) we know little of the cycles or phases of virulence or extrahuman existence of the virus. Further the importance of the intestinal route of infection is increasingly recognised. The part played by flies in carrying the virus has been ably demonstrated by Sabin and Ward and other American workers. More recent work by Ward, Melnick, and Horstmann has shown that food infected with virus is capable of transmitting the virus to flies which were fed on it (*Science*, 1945, 101, 491). To anyone with a knowledge of flies the further contamination of foodstuffs by them is no mystery.

intense headache and backache, and all other prodromal symptoms may be present, including erythematous or petechial eruptions . . . its true nature is shown by its occurrence in an epidemic focus and by the sudden termination of the disease on the third day before the appearance of the papular eruption. Such cases are apt to be encountered among recently vaccinated persons shortly after joining the staff of a smallpox hospital, and several examples have lately been reported among recently vaccinated soldiers (Vorpahl, Klaholt, Kathe)."

Harries and Mitman (1940) describe variola sine eruptione as " smallpox confined to the initial toxæmia occurs in the previously vaccinated. . . . Occasionally a few small and atypical focal lesions may appear and be possibly overlooked."

In view of the so-called abortive case in this outbreak and the extracts quoted above, it seems reasonable to conclude that such cases may show some or all of the prodromal signs and symptoms of smallpox, and that these then fade out without any appearance of the true rash. We suggest that abortive smallpox would be a better and simpler name for the conditions previously described as variola sine eruptione, variola sine variolis, and contact disease.

VACCINATION OF CONTACTS

The present outbreak led to a considerable demand for vaccination. The contacts of H. R. were numerous, and many of them unknown; and A. R., during the first three days of his illness, had attended church services, a Sunday school, a wedding, and a technical school. Vaccination was offered to all known contacts, and a special vaccination session for children was held in the technical school. The public vaccinators were hard pressed, because, besides ordinary contacts, all laundries, libraries, and salvage-collecting personnel were warned. By Feb. 23 the list of known contacts exceeded 1000, and assistance was given by the county medical and nursing staffs.

On March 3 it was decided to open special vaccination centres. Up to this time all contacts had been vaccinated at the public vaccinators' surgeries (except the special clinic held for school-children). By March 9 five centres had been opened. These were greatly appreciated, as the weather had been particularly bad and there had been long queues standing in rain and snow outside the doctors' surgeries. In the five days March 4–9, 15,000 vaccinations were performed in the district. The assistance given by the Government Lymph Establishment at Colindale Avenue, London, N.W.9, was greatly appreciated.

On the whole, everything worked well, yet experience showed where improvements might have been possible. After the first few days it was realised that it would not be possible to reinspect all vaccinated contacts; so the public were informed that the only people who would be seen again a week after their vaccinations were (1) those who had been vaccinated for the first time and whose vaccination had not taken; (2) all infants under the age of one year (for vaccination certificates); and (3) all persons vaccinated by private doctors. The vaccinators by this time consisted of public vaccinators, other practitioners, medical officers on the staffs of health departments, and medical students working under supervision. It was necessary for private doctors' patients to be seen again so that records for payment, &c., might be completed. Some improvement might have resulted from giving known contacts a document that would have given them priority in the queues.

All contacts were vaccinated in three places, and members of the general public in only one. Meanwhile the sanitary inspector's staff had been reinforced, and all contacts were visited daily for seventeen days. Any found to be ailing, however slightly, were transferred to a special contact list and visited daily by a medical officer, and returned to the original list when a negative diagnosis had been made.

As indefinite rashes from vaccination, smallpox, or for some other reason might arise, a ward of 12 beds was held in readiness at the local isolation hospital for the reception of any such cases. Three cases were admitted, and the provision of this ward proved to be a definite safeguard.

A single large room, free of unnecessary furniture, was found to be the ideal vaccination centre, with, if possible, additional shelter for applicants. The queue should be divided into smaller queues according to the number of vaccination teams. Each vaccinating team should consist of a clerical assistant (to whom the patient goes first) to enter particulars on the form, a nurse to prepare arms, the medical officer, and a volunteer to cover the vaccination mark with strapping after drying.

CONCLUSIONS

The following conclusions may be drawn from this experience:

(1) It is desirable that persons in attendance on smallpox patients on board ship should be specifically notified to the medical officers of health of the district to which they proceed when they land in this country.

(2) Vaccination in infancy may protect for very many years, but does not necessarily do so.

(3) It appears likely that one vaccination mark does not protect as completely as two or more. It seems desirable that a primary vaccination should consist of three marks, and a revaccination of at least two.

(4) During an outbreak, when there is a rush to vaccination centres, contacts should be given priority by a system of tickets.

(5) For doubtful rashes an observation ward in the nearest isolation hospital is of great value.

(6) Abortive smallpox would be a good name for the illness now known as variola sine variolis, variola sine eruptione, or contact disease.

Our thanks are due to Dr. T. Stevenson Logan, M.O.H. for Southend, for the information concerning the Southend cases.

Detection of Typhoid Carriers

THE monthly bulletin of the Ministry of Health and the Emergency Public Health Laboratory Service last November contained a note on the detection of typhoid carriers, and practitioners may like to be reminded of the suggestions made:

" A chronic carrier may cease to excrete typhoid bacilli for no apparent reason, and may resume doing so without any detectable alteration in his well-being. Epidemiological evidence, although not conclusive, suggests that the intervals of freedom may last for months or even years, but the Vi-agglutination test remains positive during these intervals. It is not proposed that any control, other than that afforded by the Public Health (Infectious Diseases) Regulations, [illegible] should be exercised over carriers, and in this connexion the attention of medical officers of health is called to pages [illegible] to 60 of the Annual Report for 1932 of the Chief Medical Officer of the Ministry where the subject is dealt with.

" *The method of detection is, before discharge from hospitals* every typhoid convalescent should have a blood test for Vi-agglutinins. If they are absent, no further action need be taken. If present (as might be expected in about one-half of the cases) a second test should be made three months later when, if they are no longer present, nothing further need be done. If, however, Vi-agglutinins are present in a titre as high as, or higher than, before, two examinations a week for three weeks, of the stools and urine or, *failing this*, [illegible] examinations with as long an interval as possible between should be made by selective cultural methods to find out whether typhoid bacilli are being excreted. If they are, the patient should be regarded as a persistent carrier; if they are not, it might be advisable to repeat the Vi-agglutination st when she had ceased having general light. The ond case developed lupus carcinoma.

Of the patients whose E.S.R. decreased, all were nically improved: and in those cases where the rate ried within normal limits or remained virtually altered, the clinical changes varied from none to parent cure.

My impression. therefore. is that the E.S.R. is of little lue in judging the progress of lupus vulgaris treated ith calciferol. The effect of calciferol on the plasma rinogen is being investigated.

Skin Department, London Hospital, E.1. P. J. FEENY.

VARIATION IN THE FEMALE PELVIS

SIR,—Whilst congratulating Dr. Nicholson and Mr. andeman Allen on their paper of August 10, I feel that ey have over-simplified both the ætiology and the variaons themselves.

No study of the pelvis, especially when its object is to retell the course of labour, can be complete unless the avity, and more particularly the sacrum, are considered. here can be little doubt that the shape of the sacrum nd its angular relation to the rest of the pelvis have a ost profound effect on the mechanism of labour; n fact, of the plates taken at an X-ray pelvimetric xamination. that giving the lateral view is of greater nportance than the others. Nowhere in their paper o Nicholson and Allen mention the sacrum or the ateral view of the pelvis.

It is true to say that what will happen to the fœtal kull at the brim of the pelvis is largely governed by the ondition in the cavity; the measurements at the brim nay be adequate whilst those in the cavity are too small o receive the skull. The size and shape of these cavityneasurements depend more on the shape and position of he sacrum than on all the other factors combined.

In my opinion it is seldom possible to place any elvis in one of the four simple groups given in this aper. The value of Caldwell and Molloy's classification ies to a great extent in its description of the parts of the pelvis other than the brim and outlet; the shape of the sacrum and the form and size of the sciatic notches are, for instance, included; and the mixed types of pelves, which form the majority, are easily and clearly described by terms such as gynæ-android.

So far as the sacrum is concerned, it has been my experience not only that there are very many different shapes and positions but that these characteristics do not follow any particular rule in relation to the type of pelvis. With the exception of a few types, such as the retroposed sacrum often found in the rickety flat pelvis, it would be very difficult to prove a nutritional cause for the many variations found in this bone.

Clinically, any pelvic examination which is concerned with the inlet and outlet only is largely a waste of time; at the brim the progress of the fœtal head can be followed during labour, and the possibilities at the outlet should have been determined clinically beforehand. It is important, however, to know what course the head will take in the pelvic cavity and what difficulties it will meet with there: this information cannot be deduced by any simple measurement of the brim or outlet, however accurate, and a prognosis based on either an opinion or on a mathematical calculation from knowledge of these two planes only can be of little value. A lateral view of the pelvis is absolutely necessary, and this must be assessed by somebody knowing the effect on the mechanism of labour of the shape and position of the sacrum.

Hope Hospital, Pendleton, Salford. GUY ROWORTH.

FIGURES, FACTS, AND FANCIES

SIR,—In your issue of August 10, Professor Heuer's painstaking and valuable monograph on the treatment of peptic ulcer is reviewed. The general tone of your review is one of pious resignation and gentle tolerance of yet "one more attempt to draw conclusions from a statistical analysis of 1139 cases." The phrases "in spite of the burden of figures" and "it is a pity that Dr. Heuer has restricted himself so rigidly to his figures" which appear in the review are typical of the frame of mind to which I refer.

I would suggest, Sir, that the tone of this review does poor service not only to the eminent journal in which it appears but to British medicine as a whole.

The day of the authoritative statement based on the occult science of clinical instinct is dying. Medical students and practitioners of the present require something more than an air of omniscience and a Harley Street address to convince them of the value of a particular line of treatment.

Those who affect to despise the critical evaluation of results by careful follow-up and assessment (a method of which Professor Heuer's monograph is a model) are careful never to be too explicit about the basis for their own views. I heard an Eminent Surgeon at an Eminent Society recently suggest that a more valuable way of forming an opinion was to investigate the incidence of private referred cases! (Dare I point out that this itself is statistics in miniature!)

May I venture to suggest, Sir, that one of the main reasons that figures are so unpopular in British medicine is that the assessment of results is time-consuming, exasperating. and unremunerative, whilst operating is rapid. pleasant, and profitable? Many a man has made a fortune with his scalpel, but the follow-up card too often brings nothing but disappointment and contumely.

It would be a good thing for British medicine if each hospital and nursing-home were compelled to publish an annual report, compiled by an impartial body, of the end-results of the treatment undertaken within its walls.

Edinburgh. D. M. DOUGLAS.

EMERGENCY BED SERVICE

SIR,—The many London doctors who made use of the Emergency Bed Service during the war must often have wondered just how long it would continue to work only by day. It was, of course, always intended that a 24-hour service should be provided, and prior to the war this was done. War-time difficulties, however, made this impossible to maintain, and for many years the service has closed at 10 P.M. Indeed, at one time it had to close at "blackout," as the windows and curtains had been blown away!

Now that it is possible to obtain the necessary staff and to run the office free from enemy interference, the committee have decided to resume the full 24-hour service, and from 9 A.M. on Sept. 1 it will be available to doctors day and night throughout the year.

The service continues to deal with all acute and urgent cases, excluding fevers, but, owing to the prevailing shortage of beds in London, it often takes considerably longer to find a bed than it did before the war, and it is quite impossible to deal with a case not in absolute need of immediate admission. Subject to these limitations, every possible assistance will be given to doctors.

Voluntary Hospitals Emergency Bed Service, R. E. PEERS
10, Old Jewry, London, E.C.2. Secretary.
(Monarch 8515.)

"MASKED" SYPHILIS

SIR,—I was much interested in the paper by Dr. E. Cronin (July 20, p. 84). It recalls a point which often eludes clinicians—namely, the masking effect of the "provocative" injection of neoarsphenamine (N.A.B.)

Many years ago a patient was sent to me with a penile ulcer, which appeared three weeks after a visit to India. Before the visit his doctor sent me a specimen of blood, which I found negative to the Wassermann and Kahn reactions. The penile ulcer was about 1 in. in diameter, with shelving edges: there was slight enlargement of the inguinal glands on both sides, but no tenderness. There was no rash or sore throat. I kept the patient two days and performed about six dark-ground examinations of material from the ulcer and from puncture of tissues near the ulcer; all were negative. I repeated the blood-tests; they too were again negative. I sent him back to his doctor with the advice that he should have no antisyphilitic treatment and that the blood-tests should be repeated every week for six weeks. The doctor adopted my suggestion about the repeated blood-tests, but, on the advice of a surgeon, he gave the patient a "provocative" injection of N.A.B. 0·3 g. the day after the repeated dark-field examinations. Needless to say, I was not told of this injection. The six weekly tests were all negative. Three months after I first saw him the patient went home to England on leave and there developed a sore throat and

The control measures operated here are a logical outcome of the discovery of the intestinal route of infection. We know already that we are at present helpless in the face of abortive and unrecognised cases to control or prevent the spread of poliomyelitis infection to our satisfaction. We cannot agree, however, that we are so beaten that we cannot even attempt experimental efforts of control.

Your leader advances the view that at present the chances of preventing poliomyelitis are remote and that this tragic disease must be accepted as " a risk inseparable from social life in human communities," without however giving any evidence or results from well-organised efforts to control it. It says also that " it seems reasonable to forecast that the disease will in the end be robbed of its virulence if not of its powers of spread "—again without any concrete basis or authority for such an assertion.

Burnet in his Dunham lectures has stated the position so clearly that it is well to quote his exact words: " epidemiologically, the paralytic disease whose incidence is described in vital statistics is merely a means of recognising the existence of virus in the community and of estimating to some extent its range of distribution and its relative virulence." Again: " it is probable that the major factor responsible for the epidemic appearance of paralysis is the occurrence of biologically irrelevant mutation in the virus to an unduly invasive type."

It has been clearly shown that the virus has been *isolated most frequently from the fæces of persons who* were close family contacts with a known paralytic case; less frequently from those with more remote contact; and very seldom among those who had no contact with a case. Far from any attempt to provide a placebo, it seems to us sound common sense and our duty to attempt to protect the rest of the community when a focus of a virulent strain is indicated by the appearance of a paralytic case.

At the risk of over-simplification, we may regard it as reasonably certain that this disease exists in the community, either in human or other carriers, in a harmless state; that it can take on a virulent phase either through a biological mutation or some unknown influence; that the occurrence of a paralytic case indicates a focus of this virulent type; and that the existence of healthy carriers of this virulent strain seems likely to be limited to those in contact with paralytic cases. We believe that efforts to organise control measures on these bases should be made, and that epidemiological control, in the present state of knowledge, can only be achieved by experimental trial of such methods as we have advocated.

While it may be accepted that at present the chances of preventing poliomyelitis are remote, there is no justification for the defeatist attitude that we should do nothing to find ways or means to control its spread. Indeed, there is not yet sufficient knowledge on poliomyelitis to justify neglect of any approach, and there is sufficient basis and justification—in spite of this scanty knowledge—to endeavour, by trial-and-error experimentation, to control the spread of the disease.

JAMES DEENY.
JOHN D. MACCORMACK.

Department of Local Government and Public Health, Dublin.

THE WEST INDIES

SIR,—Your annotation of July 27 on nutrition in the West Indies again draws attention to the poor conditions which have long existed and for which the passage of time makes it increasingly difficult to provide a real remedy. Dr. Platt in his report rightly suggests action which could be taken now to mitigate in part the effect of faulty dietetics. Despite what in the way of palliatives may be done towards raising nutritional standards in the islands under British rule, these standards are bound up with the general economic circumstances obtaining in all except Trinidad, which island still has unexhausted natural resources, and in any case has, among other advantages, a key position on trade routes. These basic advantages should in time produce their own rewards, though anyone who knows Trinidad is aware of the prejudice and usages which, somehow, must first go.

Your annotation refers to some of the factors recognised as retarding better conditions in these lovely islands which are in grave danger of becoming tropical slums. Whether we like it or not, much of the prevailing distress results from the actions of our forefathers, who, among other questionable activities, started overpopulating the islands by the uncontrolled introduction of coloured labour. It is common knowledge that, with other measures, most praiseworthy endeavours are now being made to develop crops which do not have to compete in world markets, increasingly supplied from better geographical and (in the case of sugar) subsidised sources; yet the fundamental cause of much of the trouble persists. *That is, there is an increasing population* living on overworked soil. For this reason many of us feel that the only ultimate salvation for the West Indies is to encourage emigration to the British territories on the nearby mainland which have a sufficiency of fertile soil to enable those who are transferred to become self-supporting, and, for the more ambitious, sufficient space to develop agriculture on a large enough scale to enter world consumer markets with some prospect of competing successfully. Were a university ever to be founded in the British West Indies, its dominant theme should be agricultural, rather than legal or artistic; the nucleus for this already exists.

It is a professional responsibility to see that technical advances, whether in therapeutics or dietetics, are applied as rapidly as possible, respectively at the bedside and in the realms of public health. These advances can only be employed to the best advantage when the fundamental *background receives proper attention.*

London, W.8. W. R. THROWER.

FOLIC ACID

SIR,—May we correct a statement in your annotation of June 29? Neither propionic aldehyde nor *p*-aminobenzoyl chloride were starting materials in the synthesis of pteroylglutamic acid. The immediate starting materials were *p*-aminobenzoylglutamic acid, α, β-dibromopropionaldehyde and 2, 4, 5-triamino-6-hydroxy pyrimidine. The α, β-dibromopropionaldehyde was made by brominating acrolein. The *p*-aminobenzoylglutamic acid *was made by reacting p-nitrobenzoyl chloride* and glutamic acid *to form p*-nitrobenzoylglutamic acid. this compound was then reduced to the corresponding amine.

Also, folic acid under the trade name of 'Folvite' has been available on the market since several months before our article in *Science.*

ROBERT B. ANGIER

New York, U.S.A. Lederle Laboratories Inc.

*** Folvite has not yet reached this country except in small quantities distributed for experimental purposes. We understand from Messrs. Chas. Thackray, English agents for Messrs. Lederle, that they are expecting a supply.—ED. L.

CALCIFEROL AND SEDIMENTATION-RATE

SIR,—In view of the significance attached to serial estimations of the erythrocyte-sedimentation rate (E.S.R.) in chronic infections, I should like to draw attention to the following observations extracted from an investigation I am making.

The data, which will later be more fully reported, are obtained from the first 32 of a series of patients with lupus vulgaris who have been given calciferol daily, usually in doses of 100,000 units.

After 4–7 months: (1) 50 % of the patients showed an increase in E.S.R., averaging +170 %; (2) 15 % showed a reduced rate, averaging −160 %; and (3) the remaining 35 % showed variations within normal limits or virtually *no change.*

Half the patients whose E.S.R. increased were clinically apparently cured or considerably improved. In each of these, however, the E.S.R. was normal at the commencement or after a few weeks of calciferol therapy; and in each the E.S.R. was increased beyond normal limits after 3–4 months.

Of the other half whose E.S.R. increased, 6 showed little or no clinical change, and the remaining 2 deteriorated. Of these 2, one, a female with long-standing lupus, apparently healed after a course of Finsen and general light, relapsed after $4^{1}/_{2}$ months on a maintenance dose of calciferol (50,000 units daily); her general light had been discontinued for this $4^{1}/_{2}$ months, and the relapse was in accordance with her usual history in the

ELEANOR CECILY THISTLETHWAITE

M.B. ST. AND.

Dr. Thistlethwaite, who died on June 6, was born the Philippines in 1896, and graduated M.B. at Andrews University in 1920. After holding resident sts at the Queen's Hospital for Children, Hackney, e spent five years in general practice in Gray's Inn oad and Camden Town. She held posts at the London ock Hospital and the Islington medical mission l in 1935 she became visiting medical officer to . Margaret's Hospital, Kentish Town, where she was sponsible for the care of children suffering from vulvo-aginitis and ophthalmia neonatorum. During the war, medical officer to a mobile naval train, she gave aluable service at the evacuation of the wounded after unkirk. Later, during the first London blitz, as ssistant medical officer of health for St. Pancras with pecial responsibilities for air-raid precautions, she ften remained at the first-aid stations night and day. er chief, the late Dr. Maitland Radford, formed a very igh opinion of her conduct and services through this esting time.

At the beginning of 1943 Dr. Thistlethwaite was ppointed assistant medical officer for Southend-on-Sea. n the school medical service and at the V.D. treatment entre she gained the confidence of patients, parents, nd children, and her kindly interest and wide experience f life quickly enabled her to make a unique position for erself.

VERNON THORNE THORNE

M.B. CAMB., D.T.M. & H.

Vernon Thorne Thorne was born in 1904, the son of r. Richard Thorne Thorne and grandson of Sir Richard horne Thorne, F.R.S. Educated at Marlborough and aius College, Cambridge, he followed his father and randfather to Bart's in 1926. After qualifying in 1930 e spent three years in general practice with his father Woking before joining the Colonial Medical Service. Vhen war broke out in 1939, he failed to obtain his elease to join the R.A.M.C. and continued with his uties in Nigeria and the British Cameroons, working xceedingly hard for long extended tours. Last year became seriously ill and was invalided home suffering rom a tropical form of chronic endocarditis. After hree months in hospital he returned to Woking, where e died on August 5.

He was married at St. Bartholomew's the Great in 938, and leaves a wife and daughter.

Births, Marriages, and Deaths

BIRTHS

LOOM.—On August 6, in London, the wife of Dr. Harold Bloom—a daughter.

AWKINS.—On August 10, at Oxford, the wife of Dr. G. F. C. Hawkins—a daughter.

EESON.—On August 1, at Leicester, Dr. D. Jean Leeson (*née* Mackay), the wife of Dr. Clifford A. Leeson—a son.

EWMAN.—On August 11, the wife of Mr. Philip Newman, F.R.C.S.—a son.

AUL.—On August 10, at Liverpool, the wife of Major Richard Paul, R.A.M.C.—a son.

ANDERSON.—On August 7, the wife of Dr. A. W. Sanderson, of Stocksfield, Northumberland—a son.

MARRIAGES

ALDERWOOD—SWAIN.—On August 14, at Blackpool, Robert Calderwood, M.B., Malayan Medical Service, to Marjorie Swain, M.B., of West Timperley, Cheshire.

OWARTH—HOPKINS.—On July 16, at Llanilid, Frank Hugo Howarth, M.B., major R.A.M.C., to Lucy Gwendoline Irene Hopkins.

ADDOX—SIMMONS.—On August 14, at Alderley Edge, Frederick Christopher Maddox, M.B., to Catherine Simmons, M.B.

DEATHS

URKE.—On July 22, at Manila, Philippine Islands, William Joseph Butler Burke, B.A., M.D. Dubl., aged 72.

AVIDSON.—On August 15, in Edinburgh, Arthur Davidson, M.B. Aberd., surgeon captain R.N., retired.

ORBES.—On August 13, at Weymouth, Colin Macphail Forbes, M.B. Glasg.

ARSHALL.—On August 10, in London, Robert James Marshall, M.D. Glasg., formerly of Shanghai.

AY.—On August 15, Otto May, M.D. Camb., F.R.C.P., aged 67.

ISSE.—On August 14, in London, Bertram Sydney Nissé, M.D. Lond., M.R.C.P.

AVERY.—In August, at Dun Laoghaire, co. Dublin, Frank Savery, M.R.C.S., formerly of Ealing.

AYLOR.—On August 15, at Tunbridge Wells, Frederick Howard Taylor, M.D. Lond., M.R.C.P., F.R.C.S., aged 83.

Notes and News

UNITED STATES' DIETARY

FOR some years the American housewife has been becoming increasingly nutrition-conscious, partly through newspapers and the radio, but mainly perhaps through the warm lunches provided for school-children and factory workers. The change is reflected in the altered food habits since 1909, when accurate records were first kept. The consumption of grain products has declined by a third, and there has been some reduction in the demand for meat; against this, greater variety and increased consumption of vitamins have been attained by wider distribution of milk, fruits, and vegetables. According to a review published by the Bureau of Human Nutrition and Home Economics, the total calories and protein consumed during the war period were less than at any time since 1909; but this was offset by a further increase in the distribution of almost all the protective foods.

University of London

The title of professor of clinical pathology in the university has been conferred on Dr. R. J. V. Pulvertaft, in respect of the post held by him at Westminster Hospital medical school.

The title of professor of embryology in the university has been conferred on Mr. G. R. de Beer, D.SC., F.R.S., in respect of his post at University College, as from Oct. 1, 1945.

Mr. Ian Aird has been appointed to the university chair of surgery tenable at the British Postgraduate Medical School, as from Oct. 1.

Mr. Aird qualified M.B. at Edinburgh in 1928, and was awarded the Annandale gold medal and the Wightman prize in clinical medicine. After resident appointments, including periods as house-surgeon at the Royal Infirmary and the Royal Hospital for Sick Children, Edinburgh, he attended postgraduate courses in Paris and Vienna. In 1930 he became F.R.C.S.E. From 1931 to 1935 he was senior clinical assistant and clinical tutor in the wards of Mr. J. M. Graham at the Royal Infirmary, Edinburgh. In 1934, with a Rockefeller travelling fellowship, he went for a year to the United States, where he trained under Prof. Evarts A. Graham, at St. Louis, Missouri; and he held appointments as research fellow in surgery in the University of Washington, and extra assistant in the department of surgery at Barnes Hospital. On returning to this country in 1935 he graduated CH.M., and was appointed to the staff of the Royal Edinburgh Hospital for Sick Children; in 1939 he was promoted to full charge. In the same year he became temporary assistant surgeon, and in 1943 assistant surgeon, to the professorial surgical unit in the Edinburgh municipal hospitals. From 1939 to 1943 he served with the R.A.M.C., holding the rank of lieut-colonel. Since then he has been surgeon to the E.M.S. Hospital at Gogarburn. He is lecturer on diseases in children, and assistant director of the Wilkie surgical research laboratories, at Edinburgh University.

Dr. B. S. Platt has been appointed to the chair of human nutrition tenable at the London School of Hygiene and Tropical Medicine, as from a date on which he can take up his appointment.

Dr. Platt graduated B.SC., with first-class honours in chemistry, at Leeds in 1923, and M.SC. the following year. In 1926 he became PH.D., and in 1930 qualified M.B. After a period as house-physician at Leeds General Infirmary he was appointed associate in medicine in the division of clinical research of the Henry Lester Institute of Medical Research, Shanghai. In 1938 he joined the scientific staff of the Medical Research Council, and since 1944 has been director of the human nutrition research unit. A report of his nutritional survey of the West Indies was published earlier this year.

As announced last week, Dr. Ronald Hare has been appointed to the chair of bacteriology tenable at St. Thomas's Hospital medical school, from Oct. 1.

Dr. Hare won the senior entrance scholarship at St. Mary's Hospital in 1919, and qualified M.B. Lond. in 1924. In 1926 he was awarded the Cheadle gold medal and gained a research scholarship at the institute of pathology and research, St. Mary's Hospital. He won the Katherine Bishop Harman prize in 1928, and the Nicholls prize in 1934. In 1935 he graduated M.D. After five years on the staff of the inoculation department at St. Mary's Hospital, he took part in the planning and organisation of the research laboratories at Queen Charlotte's Hospital, and was first assistant there until 1936. During this period he carried out extensive researches on the streptococci and the part they play in puerperal infection. In 1936 he went to Canada, where he has since remained, holding appointments as research associate in the Connaught laboratories and as lecturer in the department of hygiene and preventive medicine in the University of Toronto. In addition to undertaking research on the virus of influenza and the large-scale manufacture of influenza vaccine, he was for a time in charge of the planning and organisation of the penicillin plant set up at the University of Toronto by the Canadian Government in 1943. His published work includes contributions on the classification of the hæmolytic streptococci, the mechanism of wound infection, the spread of nasopharyngeal infection, and the epidemiology of influenza.

Dr. J. M. Robson has been appointed to the readership in pharmacology, tenable at Guy's Hospital medical school, as from Oct. 1.

A VERSATILE CARCINOGEN.—In the second paragraph of our annotation of August 17 (p. 242) the word "Leeds" should be substituted for "Sheffield."

rash; he consulted a specialist who found his Wassermann and Kahn blood-tests strongly positive and diagnosed syphilis, much to the discomfiture of the patient. This case was later quoted against me, as an example of malpraxis.

In an article on the prophylactic treatment of accidental inoculations with *Treponema pallidum* (*Trans. Ass. Amer. Phys.* 1938, 53, 281) H. J. Morgan expresses his belief in immediate treatment with intravenous N.A.B. 0·6 g. followed by a course of three injections of N.A.B. 0·6 g. He cites L. Fournier and L. Guenot (*Pr. méd.* 1919, 27, 354), who treated 40 women just after intercourse with a male with a penile chancre. Of these women, 5 refused treatment, and the other 35 received either arsphenamine 1·0–1·2 g., or N.A.B. 1·2–2·0 g. The 5 untreated all developed syphilis; none of the treated women developed syphilis.

It would appear that the "provocative" dose of N.A.B. has no place in the treatment (or diagnosis) of syphilis; the so-called Jarisch-Herxheimer reaction, if it occurred, must have passed unnoticed by the patient and his attendants in my case; and I think the N.A.B. 0·3 g. certainly helped to obscure the diagnosis. For those who can learn, the educational value of such a series as Dr. Cronin's is inestimable.

Palmer's Hill, Epping. FRANK MARSH.

THE COMMON COLD

SIR,—A new attack is to be made on the common cold by a research unit established by the Medical Research Council at the Harvard Hospital, Salisbury. May I call attention to a method of treatment which I have found effective in many cases over many years?

As soon as the first signs of a cold are apparent the patient should gargle, two-hourly, with a solution of 20–25 drops of liquor ammoniæ dilutus *B.P.* in half a tumbler of water. By this simple and harmless remedy the symptoms are as a rule relieved or removed within a few hours. The many other solutions, including antiseptics, which I have tried in the same way have not had the same success, and the effect of ammonia on the swollen mucous membrane of the *nasopharynx* may perhaps be related to its effect on acute urticaria or on the weals caused by stings or the injection of histamine.

London, W.1. B. O. C. PRIBRAM.

C.CM. OR MILLILITRE?

SIR,—Dr. J. M. Hamill, in his letter of August 17, attributes to me a statement or thought which I have not expressed. I am not concerned with the impropriety of converting c.cm. to millilitres by using the proper conversion factor. It is clearly not improper to do so, it is merely tedious. The only point at issue between us is that in my opinion, as the volume of the c.cm. is not a millilitre (on this we are agreed), it is inaccurate for a clinician to say when he has injected so many c.cm. of a substance that he has injected the same number of millilitres.

London, W.1. G. E. BEAUMONT.

RESEARCH ON TUBERCULOSIS

SIR,—Dr. Newell's suggestion that an Institute for Tuberculosis Research should be founded in this country will find considerable support, for many are making gallant lone efforts to explore some part of the vast field of tuberculosis but there is at present no body which is coördinating these excellent efforts.

Research requires not only enthusiastic workers but also direction and adequate financial support. It would probably not be difficult to gather together a number of experts who would be capable of directing research, but to find the financial backing such a body needs is not going to be easy. But why start another tuberculosis organisation when there are already three which include amongst their members almost every enthusiastic tuberculosis physician in this country?

As long ago as May 30, 1942, a leader in THE LANCET entitled Three Over-Lords said that the action of the three organisations (the National Association for the Prevention of Tuberculosis, the Joint Tuberculosis Council, and the Tuberculosis Association) had been "likened, trenchantly but not unkindly, to the fibrillating auricle—individual ineffective twitchings keeping a sluggish stream on the move"! Would not the formation of a new body add to these "ineffective twitchings"? This applies particularly to research, and the deduction "How much better would be the powerful systole of combined action" is specially significant in this particular field of tuberculosis work. The combined action of these three associations could do much to control and correlate Tuberculosis Research, but the provision of the necessary funds still remains a problem which I suggest should, in the first instance, be a matter for discussion with the Government; and the Three Over-Lords are the channels through which such discussion should be inaugurated.

Dr. Newell will do good service if he is able to collect the names of those interested in his plea for an Institute for Tuberculosis Research and if he would present their *demands to one, or all, of the associations* I have mentioned. If these bodies could take united action it is possible that his efforts will not have been in vain.

Berkhamsted. FREDERICK HEAF.

OUR HOUSES

SIR,—I was particularly interested in your leading article of July 27 on The Cult of the Obsolete. I would *like to add one specific item—namely, that every house,* no matter how small, should have two W.C.'s—one inside and one outside, for preference. Most of the even small houses built in the mid-Victorian era have a W.C. inside and one outside, but the majority of the houses built during the years 1914–39 (the "ribbon development" period) have only one.

An extra W.C. is a very great asset, and I submit that in many houses it would help to form regular habits during the early morning rush hours.

Plumstead, London, S.E.18. C. J. SAWARD.

Obituary

BERTRAM SYDNEY NISSÉ

M.D. LOND., M.R.C.P.

Dr. Bertram Nissé, physician to the Red Cross Clinic for Rheumatic Diseases, died in London on August 1 Educated at St. Olave's School, London, he entered the London Hospital with a Buxton arts scholarship and qualified in 1921. A year later he took his M.B., and in 1924 he was awarded the university gold medal for his M.D. thesis. He obtained the M.R.C.P. in 1925, and after holding house-appointments and a pathological assistantship at the London Hospital he became resident medical officer at the National Hospital for Diseases of the Heart, for cardiology and the chronic rheumatic diseases were already his main interests. Later he was promoted to chief assistant at the National Heart Hospital. Convinced of the practical importance of developing teaching and research in the rheumatic disorders and of improving standards of practice, he was one of the original *team of physicians who in 1930 founded the* B.R.C.S. clinic. During the war years, in the absence of Dr. W. S. C. Copeman on service, he was also in charge of the rheumatism clinic at the West London Hospital. A member of the International Society for Medical Hydrology, he was also a vice-president of the physical medicine section of the Royal Society of Medicine. In his monograph, published in 1938, he compressed into small compass the salient features of the chronic rheumatic diseases together with their physical treatment.

K. S. writes: "A fine physician, in both character and learning, Nissé gave to every patient the benefit of his wide knowledge of general medicine. For each he spared himself no effort to work out a comprehensive scheme of treatment, never falling into the common error of assigning an unduly dominant place to one branch of therapeutics. He was equally unstinting of his natural kindliness and sympathy, and was the same unruffled, dependable friend to all who sought his help even in his last year of ill health and anxiety. His untimely death comes at a moment when there is an awakening throughout the land to the need for a national campaign against rheumatism; his example and his work can ill be spared."

Dr. Nissé married in 1932 Miss Hélèna Jacobs, of Newcastle, and he leaves her with a son and a daughter.

MYTH AND MUMPSIMUS *

JOHN R. FORBES
M.D.Lond., M.R.C.P.
MEDICAL REGISTRAR, GUY'S HOSPITAL

ONE of the few advantages of world unrest is that it isturbs complacency and raises doubt. The last twenty ears, filled as they have been with the strife of men and he clash of opposing ideologies, have seen in all fields of uman activity greater changes in beliefs and greater uestionings of dogmas than perhaps any other period of istory. Such tendency to iconoclasm is clearly maniested in medicine. Where is the elaborate prescription f yesteryear, where the once universal ritual of purgation, vhere the quondam rigid line of distinction between "organic" and "functional" disease? For very many years they survived destruction, but doubt has been too much for them, and now they join phlebotomy and exorcism in limbo. A like tendency is clear in surgery. The position of Fowler, for so long unassailed, is today seriously endangered (Spalding 1946). The emptiness of many traditional doctrines is being exposed, and Truth peeps out from the well of superstition and ignorance.

ELIMINATION OF TOXINS

Yet the myth and the mumpsimus in medicine die hard, as reference to almost any recent textbook or a visit to the wards of a modern hospital will show. For example, the traditional forcing of fluids upon patients (with or without pyrexia) in the hope of thereby "aiding in the elimination of toxins" is still a popular custom. It is important to be clear in this matter. The replacement of fluid lost from the body by a sweating, pyrexial patient is, of course, essential. It is equally necessary to maintain a free flow of urine when a drug such as a sulphonamide, capable, in too great concentration, of damaging the kidneys, is being given. But the conception of the body as some sort of involved water-closet, to be cleansed by flushing with copious draughts of Imperial drink, is quite out of date.† We have given up belabouring the colon with purgatives and douches, and the sweat glands with diaphoretics and hot baths, in this quixotic battle against elusive toxins. It is time that the kidneys were rescued from similar assaults, and the patient allowed to sleep undisturbed by frequent recourse to the urine-bottle.

Here it is interesting to note that although ritual purgation has largely disappeared from the modern practice of medicine, it unaccountably lingers in the treatment of acute food-poisoning. The initial dose of salts, or, *horribile dictu*, of castor oil, is still very commonly dispensed, though how the agitated intestine, already acutely inflamed and pouring forth fluid in an all-out effort to get rid of the offending bacteria, can be expected to welcome further chemical irritation is hard to see. A similar mystical belief in the virtues of magnesium sulphate in promoting "a free flow of bile" is responsible for its routine exhibition in such conditions as infective hepatitis. Epsom salts cause the gall-bladder to contract and to expel bile into the duodenum; but this is not likely to benefit inflamed liver-cells. The custom is based on ancient misconceptions of the pathogenesis of such disorders; yet it still persists.

In the matter of diet, superstition still plays an active part. The 1946 edition of a famous and justly popular British textbook of medicine admonishes its readers to forbid their hypertensive patients, among other things, "twice-cooked meat, salted and preserved meat, liver, kidneys, brains, sweetbreads, meat soup and gravies; seasonings of various kinds, and meat extractives." In fact, "all those articles of food which especially stimulate the cardiovascular system should be reduced, and proportionately to the degree of hypertension." On the other hand, "fish, poultry, game (not high), rabbit . . ." are permissible. Now, is there the slightest reliable evidence that the kind of food he eats makes the least difference to the patient with essential hypertension, so long as the total quantity is not excessive? What grounds are there for believing that certain articles of diet "especially stimulate the cardiovascular system"? Is not, in fact, all the foregoing a great deal of nonsense? Even supposing we can, by eliminating all protein foods, reduce our patient's blood-pressure a few millimetres, it is very doubtful if he will be any the better for it. It is the whole man that we must view, and not merely the minor variations of a column of mercury.

EXAMINING THE DIET

One might go further and ask whether we have reason to think that diet is of any real importance in those diseases which are not associated with gastro-intestinal dysfunction or with a definite upset of metabolism. Do our frequently elaborate dietary instructions serve, in most cases, any other purpose than to provide our patients with food for mutual gossip and discussion and, in wartime, with insoluble problems in catering? I do not believe that the enforced disappearance, due to rationing and food shortage, of finicking dietary régimes in the last few years has led to any appreciable increase in death or disease. In fact, I strongly suspect that many patients are the better for it. I have not observed, for example, that my peptic-ulcer patients relapse any more frequently since I perforce ceased to recommend a carefully selected diet for six months or longer, and now merely advise them to eat, within reason, whatever food they find does not disagree. On the contrary, they seem to be better; because no longer do they feel obliged to consider their stomach before all else, and to debate at every turn the "digestibility" of each dish before them. They cease to fuss and fad, to undernourish themselves by exaggerated dietary precautions, and to harass themselves with longings for unnecessarily forbidden fruit. They are no longer dialling TUM every few minutes, and their ulcers are duly carefree.

We are sometimes in danger of forgetting that the appetite, when not perverted by gluttony or hysterical asceticism, or falsely determined by injudicious medical advice, is a remarkably reliable guide to what is and what is not good for a sick person. If a uræmic patient should desire roast beef (an admittedly unlikely event), roast beef will do him no harm. If the case of infective hepatitis would like eggs and bacon, he should not be forbidden them. In most illnesses, especially if the patient be in hospital, anorexia, partly due to the illness perhaps, but more often the result of monotonous and unimaginative cookery, is a far more formidable obstacle to recovery than is the hypothetically injurious effect of protein and fat. That there are occasions when certain kinds of food must be withheld nobody will deny. The acute nephritic with severe oliguria will not respond well to a nitrogenous diet. But then he is in the highest degree unlikely to desire it. To withhold, however, protein foods from the patient with congestive heart-failure, on the very dubious grounds that such foods "increase metabolism and throw extra work on the heart," is entirely unjustifiable. One could adduce many other examples of such needless dietary restrictions. It is surely simple common sense that a patient who is eating the food he likes and enjoying it will be happier and will tend to recover more quickly than one who is condemned to a rigid, monotonous diet—a diet often based on armchair theory, or on dubious feeding experiments with rats, or simply on superstition, and bearing little or no relation to clinical reality. It is so easy to forbid; and the mere act of doing so gives an illusion of positive action which

---

* *Mumpsimus:* A traditional custom, obstinately adhered to however unreasonable it may be (O.E.D.).

† Compare the beliefs of Dr. Sangrado in *Gil Blas* (c. 1700).

University of Cambridge

At a congregation on August 3 the following degrees were conferred:

M.D.—K. G. Bergin, G. E. Burton, P. T. Cooper, E. M. Darmady, John Murray, A. M. Payne, A. C. Thackray, R. M. Todd.

M.B., B.Chir.—A. V. G. Bibby, B. H. Brock, J. A. Bulleid, I. F. J. Churchill-Davidson, L. W. Clarke, D. E. Cullington, P. L. M. Hartley, P. M. R. Hemphill, S. L. Hetherington, J. D. Lever, R. H. G. Lyne-Pirkis, R. W. J. Maclure, I. M. Ormerod, Roy Randell, C. E. D. Taylor, H. B. Whitmore (in person); D. M. C. Ainscow, G. S. Andrew, D. K. Briggs, E. H. W. Burt, H. C. Churchill-Davidson, J. W. Coleman, D. J. Crockett, P. S. Davis, J. R. B. Dixey, W. M. Edgar, A. C. Franks, J. B. Frost, T. C. Gibson, E. C. Glover, Leonhard Haas, A. W. I. Hall, P. S. Hall, W. J. Hay, Michael Hemming, E. M. James, K. E. Jefferson, A. G. Jessiman, G. L. Leathart, A. H. Littlewood, Cecil McIver, W. D. Mail, K. E. Marsh, E. P. G. Michell, D. T. Milnes, D. V. Milward, D. R. Morgan, Philip Rhodes, J. S. Rivers, O. C. A. Scott, J. G. Selwyn, Malcolm Shirley, D. R. Smith, J. S. Swallow, R. J. D. Temple, M. K. Towers, H. W. Trusted, Sam Vakil, John Vallance-Owen, Walter van't Hoff, D. R. Wallace-Jones, D. B. Wallis, W. R. Wardill, I. W. Whimster, Humphrey Whitmore, R. J. Williams (by proxy).

Titles of degrees were conferred on the following:

M.B., B.Chir.—C. M. E. Jones, G. A. Meigh, Mrs. M. H. Miller, Mrs. A. M. P. Pantin.

The E. G. Fearnsides scholarship has been awarded to Dr. Lionel Wolman.

University of Leeds

As announced recently, Dr. H. V. Dicks has been appointed to the new chair of psychiatry.

Dr. Dicks studied medicine at Cambridge University; he was a foundation scholar of St. John's College, where he took the natural sciences tripos. Later, he went to St. Bartholomew's Hospital, winning the Baly research scholarship, the Brackenbury scholarship in medicine, and the Kirkes gold medal. He qualified M.R.C.S. in 1926, and M.B. in 1927, when he also became a M.R.C.P., and graduated M.D. After holding appointments as house-physician at Bethlem Royal Hospital, and as house-physician, demonstrator in pathology, and chief assistant to a medical unit at St. Bartholomew's Hospital, he joined the staff of the Tavistock Clinic in 1928, becoming assistant medical director in 1930. The results of his work were published in 1939 under the title *Clinical Studies in Psychopathology* and in many contributions to the literature. In 1940 he left the E.M.S. to joint the Army, in which he served with the rank of lieut.-colonel. His work included studies of the psychological structure of German and National Socialist groups and communities in relation to military and political planning, and in 1945 he became consultant in psychiatry to the German personnel research section of the Control Commission. Since leaving the Army he has returned to the Tavistock Clinic, and has also joined the staff of the new Tavistock Institute of Human Relations.

University of Edinburgh

Dr. Richard Ellis has been appointed to the Edward Clark chair of child life and health, in succession to Prof. Charles McNeil, who is retiring on Sept. 30.

Dr. Ellis was educated at Leighton Park and at King's College, Cambridge. He qualified from St. Thomas's Hospital in 1926, and after holding house-appointments at St. Thomas's went to the United States, where he worked as a research fellow in pædiatrics at Harvard medical school in 1928 and 1929, and was intern at the Children's Hospital, Boston, Mass. After returning to this country he was registrar and first assistant to the children's department of the London Hospital. In 1930–31 he held a Wander research scholarship at Westminster Hospital, and thereafter went back to St. Thomas's as registrar in the children's department. In 1931 he graduated M.D. and became M.R.C.P. He was pathologist and inpatient's medical registrar to the Hospital for Sick Children, Great Ormond Street, before his appointment to the honorary staffs of the Infants' Hospital and of Guy's Hospital, where he is physician in charge of the children's department. With Dr. Audrey Russell (now Mrs. Ellis) he supervised the medical side of the evacuation of Basque children from Bilbao in 1937 during the civil war in Spain, and later he worked for Polish child refugees in Rumania and Hungary. Elected F.R.C.P. in 1939, he joined the Royal Air Force in 1940, and served, with the rank of wing-commander, in North Africa, Italy, and Belgium, being mentioned in despatches and appointed O.B.E. Dr. Ellis is editor of the *Archives of Disease in Childhood*, and has himself written extensively, particularly on nutritional and metabolic disorders and problems of development in infancy. He has lately joined central executive of the National Society for Prevention of Cruelty to Children.

Return to Practice

The Central Medical War Committee announces that the following have resumed civilian practice:

Mr. H. JACKSON BURROWS, F.R.C.S., 16, Park Square East, Regent's Park, N.W.1.

Mr. JOHN HOWKINS, F.R.C.S., 109, Harley Street, W.1. (Welbeck 7395—day; Wimbledon 1613—night.)

Dr. H. F. TURNEY, 53, Queen Anne Street, Cavendish Square, W.1.

Surgical Instruments Panel

A panel has been appointed by the Interdepartmental Committee on Scientific Instruments, with the objects of promoting the manufacture of surgical and dental instruments and of placing these industries on a sound economic basis. Questionaries have been sent to a number of manufacturers; any others who would like to assist with information should communicate with the secretary, Surgical and Dental Instrument Panel, room 507, Portland House, Tothill Street, London, S.W.1.

A Course at Cambridge

A fortnight's general refresher course will be held at Add brooke's Hospital, beginning on Oct. 14. This course open to medical officers released from the Forces, and National Health Insurance practitioners who will receive same allowances as are paid to doctors released from Services. Application should be made to Dr. A. C. D. F Trinity Hall, Cambridge. (Tel. 5047.)

Airborne Medical Society

A permanent Airborne Medical Society is being formed whose membership will be open to all medical and de officers who have been entitled to wear the *maroon* be Further information may be had from the hon. secretary, Mr. Guy Rigby-Jones, M.C., F.R.C.S.E., 63A, Belsize Pa Gardens, London, N.W.3.

Franco-Anglo-American Medical Society

The third quarterly meeting of this society will be held 11, Chandos Street, London, W.1, on Tuesday, Sept. at 2.30 P.M.; when Lord Horder will take the chair.

Ministry of Health

Mr. H. Symon has been appointed under-secretary *in the ministry, and Miss Enid Russell-Smith* an *addition* under-secretary in the health services division.

Dr. J. D. ROBERTSON, of the Courtauld institute of the Middlesex Hospital, is shortly leaving for the United States where he will lecture for the University of California at San Francisco and Los Angeles and will deliver a Mayo Foundation lecture at Rochester, Minn.

Medical Diary

AUGUST 25 TO 31

Thursday, 29th

EDINBURGH POSTGRADUATE LECTURES

4.30 P.M. (Royal Infirmary.) Dr. J. D. S. Cameron: Treatment of Amœbiasis.

Appointments

CLARKE, H. OSMOND, M.B. Dubl., F.R.C.S.: surgeon to the Lo Hospital, and asst. director of the orthopædic and acci dept.

DAVIDSON, J. ROMANES, M.D. Edin.: *medical superintendent* Orphan Homes of Scotland and Colony for Epileptics, Bri of Weir, Renfrewshire.

HANNESSON, HANNES, M.R.C.S.: medical superintendent, Croydon County Borough Sanatorium, North Cheam, Surrey.

KERSHAW, J. D., M.D. Lond., D.P.H.: M.O.H. and school M.O., Colchester, Essex.

Hospital for Sick Children, Great Ormond Street, London:

- ABERMAN, DAVID, M.D. Camb., D.A.: anæsthetist.
- BLAIR, L. G., M.R.C.S., D.M.R.E.: director, dept. of radiology.
- CREAK, E. MILDRED, M.D. Lond., M.R.C.P., D.P.M.: physician dept. of psychological medicine.
- EVANS, PHILIP, M.D. Manc., F.R.C.P.: physician to outpatients
- HENRY, T. C., M.R.C.S., L.D.S.: dental surgeon.
- KIERNANDER, F. B., M.B. Lond., M.R.C.P., D.M.R.E., D.PHYS.MED.: director, dept. of physical medicine.
- LUCAS, B. G. B., M.R.C.S., D.A.: anæsthetist.

Colonial Service:

- AUSTIN, T. A., L.R.C.P.I., D.T.M. & H., D.P.H.: D.M.S., Uganda.
- BASSETT, Captain T. H., M.B. Lond.: M.O., Tanganyika.
- BOSSMAN, J. E., L.R.C.P.: M.O., Gold Coast.
- BRODIE, ALISON G., M.B. Aberd.: M.O., Malaya.
- CAUCHI, F. J., M.D. Malta: M.O., Nigeria.
- CLARK, Major J., M.B., D.P.H.: M.O., Nigeria.
- DAVIES, Captain A. G. M., M.B. Brist.: M.O., Tanganyika.
- DAVIES, H. N., M.B. Edin., D.T.M.: medical specialist, Tanganyika.
- DRYDEN, S., M.B.: asst. M.O., Jamaica.
- DUNNETT, Major A. H., M.B. Aberd.: M.O., Gold Coast.
- DYKES, W. S., M.B. Glasg.: M.O., Malaya.
- ELBERT, J. J., M.B.E., M.B. Glasg.: M.O., Nigeria.
- FITTON, J. M., M.B. Leeds, F.R.C.S.: orthopædic surgeon, Mauritius.
- FRAZER, Major S. M., M.R.C.S.: M.O., Bermuda.
- GORDON, S. G., L.R.C.P.: M.O., Gambia.
- HOUSTON, Captain G. F., M.R.C.S.: M.O., Nigeria.
- JACKSON, Major G. C. A., M.B. Lond.: M.O., Northern Rhodesia.
- MCGARITY, J. F., M.B.: M.O., Malaya.
- THOMPSON, Captain D. E., M.B. Camb.: M.O., Tanganyika.
- TIMMIS, W. G., M.B. Lpool: M.O., Uganda.
- UPTON, Flight-Lieutenant B. H. B., M.B. Birm.: M.O., Fiji.
- VAN SOMEREN, Lieut.-Colonel R. K. A., F.R.C.S.E.: M.O., Kenya.
- WILLETT, K. C., M.R.C.S.: trypanosomiasis officer, Tanganyika.
- WRIGHT, Captain R.: M.O., Nyasaland.

Examining Factory Surgeons:

- JOBSON, C. F., M.R.C.S.: Trowbridge, Wilts.
- LLOYD, D. H., M.R.C.S.: Carmarthen.
- MAIN, B. CAMPDEN, M.R.C.S.: Earl's Colne, Essex.
- ROSS, M. S., M.B. Edin., F.R.C.S.E.: Hemsworth, Yorks.

MYTH AND MUMPSIMUS *

JOHN R. FORBES
M.D. Lond., M.R.C.P.
MEDICAL REGISTRAR, GUY'S HOSPITAL

ONE of the few advantages of world unrest is that it disturbs complacency and raises doubt. The last twenty years, filled as they have been with the strife of men and the clash of opposing ideologies, have seen in all fields of human activity greater changes in beliefs and greater questionings of dogmas than perhaps any other period of history. Such tendency to iconoclasm is clearly manifested in medicine. Where is the elaborate prescription of yesteryear, where the once universal ritual of purgation, where the quondam rigid line of distinction between "organic" and "functional" disease ? For very many years they survived destruction, but doubt has been too much for them, and now they join phlebotomy and exorcism in limbo. A like tendency is clear in surgery. The position of Fowler, for so long unassailed, is today seriously endangered (Spalding 1946). The emptiness of many traditional doctrines is being exposed, and Truth peeps out from the well of superstition and ignorance.

ELIMINATION OF TOXINS

Yet the myth and the mumpsimus in medicine die hard, as reference to almost any recent textbook or a visit to the wards of a modern hospital will show. For example, the traditional forcing of fluids upon patients (with or without pyrexia) in the hope of thereby "aiding in the elimination of toxins" is still a popular custom. It is important to be clear in this matter. The replacement of fluid lost from the body by a sweating, pyrexial patient is, of course, essential. It is equally necessary to maintain a free flow of urine when a drug such as a sulphonamide, capable, in too great concentration, of damaging the kidneys, is being given. But the conception of the body as some sort of involved water-closet, to be cleansed by flushing with copious draughts of Imperial drink, is quite out of date.† We have given up belabouring the colon with purgatives and douches, and the sweat glands with diaphoretics and hot baths, in this quixotic battle against elusive toxins. It is time that the kidneys were rescued from similar assaults, and the patient allowed to sleep undisturbed by frequent recourse to the urine-bottle.

Here it is interesting to note that although ritual purgation has largely disappeared from the modern practice of medicine, it unaccountably lingers in the treatment of acute food-poisoning. The initial dose of salts, or, *horribile dictu*, of castor oil, is still very commonly dispensed, though how the agitated intestine, already acutely inflamed and pouring forth fluid in an all-out effort to get rid of the offending bacteria, can be expected to welcome further chemical irritation is hard to see. A similar mystical belief in the virtues of magnesium sulphate in promoting "a free flow of bile" is responsible for its routine exhibition in such conditions as infective hepatitis. Epsom salts cause the gall-bladder to contract, and to expel bile into the duodenum ; but this is not likely to benefit inflamed liver-cells. The custom is based on ancient misconceptions of the pathogenesis of such disorders ; yet it still persists.

In the matter of diet, superstition still plays an active part. The 1946 edition of a famous and justly popular British textbook of medicine admonishes its readers to forbid their hypertensive patients, among other things, "twice-cooked meat, salted and preserved meat, liver, kidneys, brains, sweetbreads, meat soup and gravies ; seasonings of various kinds, and meat extractives." In fact, "all those articles of food which especially stimulate the cardiovascular system should be reduced, and proportionately to the degree of hypertension." On the other hand, "fish, poultry, game (not high), rabbit . . ." are permissible. Now, is there the slightest reliable evidence that the kind of food he eats makes the least difference to the patient with essential hypertension, so long as the total quantity is not excessive ? What grounds are there for believing that certain articles of diet "especially stimulate the cardiovascular system" ? Is not, in fact, all the foregoing a great deal of nonsense ? Even supposing we can, by eliminating all protein foods, reduce our patient's blood-pressure a few millimetres, it is very doubtful if he will be any the better for it. It is the whole man that we must view, and not merely the minor variations of a column of mercury.

EXAMINING THE DIET

One might go further and ask whether we have reason to think that diet is of any real importance in those diseases which are not associated with gastro-intestinal dysfunction or with a definite upset of metabolism. Do our frequently elaborate dietary instructions serve, in most cases, any other purpose than to provide our patients with food for mutual gossip and discussion and, in wartime, with insoluble problems in catering ? I do not believe that the enforced disappearance, due to rationing and food shortage, of finicking dietary régimes in the last few years has led to any appreciable increase in death or disease. In fact, I strongly suspect that many patients are the better for it. I have not observed, for example, that my peptic-ulcer patients relapse any more frequently since I perforce ceased to recommend a carefully selected diet for six months or longer, and now merely advise them to eat, within reason, whatever food they find does not disagree. On the contrary, they seem to be better ; because no longer do they feel obliged to consider their stomach before all else, and to debate at every turn the "digestibility" of each dish before them. They cease to fuss and fad, to undernourish themselves by exaggerated dietary precautions, and to harass themselves with longings for unnecessarily forbidden fruit. They are no longer dialling TUM every few minutes, and their ulcers are duly carefree.

We are sometimes in danger of forgetting that the appetite, when not perverted by gluttony or hysterical asceticism, or falsely determined by injudicious medical advice, is a remarkably reliable guide to what is and what is not good for a sick person. If a uræmic patient should desire roast beef (an admittedly unlikely event), roast beef will do him no harm. If the case of infective hepatitis would like eggs and bacon, he should not be forbidden them. In most illnesses, especially if the patient be in hospital, anorexia, partly due to the illness perhaps, but more often the result of monotonous and unimaginative cookery, is a far more formidable obstacle to recovery than is the hypothetically injurious effect of protein and fat. That there are occasions when certain kinds of food must be withheld nobody will deny. The acute nephritic with severe oliguria will not respond well to a nitrogenous diet. But then he is in the highest degree unlikely to desire it. To withhold, however, protein foods from the patient with congestive heart-failure, on the very dubious grounds that such foods "increase metabolism and throw extra work on the heart," is entirely unjustifiable. One could adduce many other examples of such needless dietary restrictions. It is surely simple common sense that a patient who is eating the food he likes and enjoying it will be happier and will tend to recover more quickly than one who is condemned to a rigid, monotonous diet—a diet often based on armchair theory, or on dubious feeding experiments with rats, or simply on superstition, and bearing little or no relation to clinical reality. It is so easy to forbid ; and the mere act of doing so gives an illusion of positive action which

---

* *Mumpsimus*: A traditional custom, obstinately adhered to however unreasonable it may be (O.E.D.).

† Compare the beliefs of Dr. Sangrado in *Gil Blas* (c. 1700).

University of Cambridge

At a congregation on August 3 the following degrees were conferred:

M.D.—K. G. Bergin, G. E. Burton, P. T. Cooper, E. M. Darmady, John Murray, A. M. Payne, A. C. Thackray, R. M. Todd.

M.B., B.Chir.—A. V. G. Bibby, B. H. Brock, J. A. Bulleid, I. F. J. Churchill-Davidson, L. W. Clarke, D. E. Cullington, P. L. M. Hartley, P. M. R. Hemphill, S. L. Hetherington, J. D. Lever, R. H. G. Lyne-Pirkis, R. W. J. Maclure, I. M. Ormerod, Roy Randell, C. E. D. Taylor, H. B. Whitmore (in person); D. M. C. Ainscow, G. S. Andrew, D. K. Briggs, E. H. W. Burt, H. C. Churchill-Davidson, J. W. Coleman, D. J. Crockett, P. S. Davis, J. R. B. Dixey, W. M. Edgar, A. C. Franks, J. B. Frost, T. C. Gibson, E. C. Glover, Leonhard Haas, A. W. I. Hall, P. S. Hall, W. J. Hay, Michael Hemming, E. M. James, K. E. Jefferson, A. G. Jessiman, G. L. Leathart, A. H. Littlewood. Cecil McIver, W. D. Mall, K. E. Marsh, E. P. G. Michell, D. T. Milnes, D. V. Milward, D. R. Morgan, Philip Rhodes, J. S. Rivers, O. C. A. Scott, J. G. Selwyn, Malcolm Shirley, D. R. Smith, J. S. Swallow, R. J. D. Temple, M. K. Towers, H. W. Trusted, Sam Vakil, John Vallance-Owen, Walter van't Hoff, D. R. Wallace-Jones, D. B. Wallis, W. R. Wardill, I. W. Whimster, Humphrey Whitmore, R. J. Williams (by proxy).

Titles of degrees were conferred on the following:

M.B., B.Chir.—C. M. E. Jones, G. A. Meigh, Mrs. M. H. Miller, Mrs. A. M. P. Pantin.

The E. G. Fearnsides scholarship has been awarded to Dr. Lionel Wolman.

University of Leeds

As announced recently, Dr. H. V. Dicks has been appointed to the new chair of psychiatry.

Dr. Dicks studied medicine at Cambridge University; he was a foundation scholar of St. John's College, where he took the natural sciences tripos. Later, he went to St. Bartholomew's Hospital, winning the Baly research scholarship, the Brackenbury scholarship in medicine, and the Kirkes gold medal. He qualified M.R.C.S. in 1926, and M.B. in 1927, when he also became a M.R.C.P., and graduated M.D. After holding appointments as house-physician at Bethlem Royal Hospital, and as house-physician, demonstrator in pathology, and chief assistant to a medical unit at St. Bartholomew's Hospital, he joined the staff of the Tavistock Clinic in 1928, becoming assistant medical director in 1930. The results of his work were published in 1939 under the title *Clinical Studies in Psychopathology* and in many contributions to the literature. In 1940 he left the E.M.S. to joint the Army, in which he served with the rank of lieut.-colonel. His work included studies of the psychological structure of German and National Socialist groups and communities in relation to military and political planning, and in 1945 he became consultant in psychiatry to the German personnel research section of the Control Commission. Since leaving the Army he has returned to the Tavistock Clinic, and has also joined the staff of the new Tavistock Institute of Human Relations.

University of Edinburgh

Dr. Richard Ellis has been appointed to the Edward Clark chair of child life and health, in succession to Prof. Charles McNeil, who is retiring on Sept. 30.

Dr. Ellis was educated at Leighton Park and at King's College, Cambridge. He qualified from St. Thomas's Hospital in 1926, and after holding house-appointments at St. Thomas's went to the United States, where he worked as a research fellow in pædiatrics at Harvard medical school in 1928 and 1929, and was intern at the Children's Hospital, Boston, Mass. After returning to this country he was registrar and first assistant to the children's department of the London Hospital. In 1930–31 he held a Wander research scholarship at Westminster Hospital, and thereafter went back to St. Thomas's as registrar in the children's department. In 1931 he graduated M.D. and became M.R.C.P. He was pathologist and inpatient's medical registrar to the Hospital for Sick Children, Great Ormond Street, before his appointment to the honorary staffs of the Infants' Hospital and of Guy's Hospital, where he is physician in charge of the children's department. With Dr. Audrey Russell (now Mrs. Ellis) he supervised the medical side of the evacuation of Basque children from Bilbao in 1937 during the civil war in Spain, and later he worked for Polish child refugees in Rumania and Hungary. Elected F.R.C.P. in 1939, he joined the Royal Air Force in 1940, and served, with the rank of wing-commander, in North Africa, Italy, and Belgium, being mentioned in despatches and appointed O.B.E. Dr. Ellis is editor of the *Archives of Disease in Childhood*, and has himself written extensively, particularly on nutritional and metabolic disorders and problems of development in infancy. He has lately joined central executive of the National Society for Prevention of Cruelty to Children.

Return to Practice

The Central Medical War Committee announces that the following have resumed civilian practice:

Mr. H. JACKSON BURROWS, F.R.C.S., 16, Park Square East, Regent's Park, N.W.1.
Mr. JOHN HOWKINS, F.R.C.S., 109, Harley Street, W.1. (Welbeck 7395—day; Wimbledon 1613—night.)
Dr. H. F. TURNEY, 53, Queen Anne Street, Cavendish Square, W.1.

Surgical Instruments Panel

A panel has been appointed by the Interdepartmental Committee on Scientific Instruments, with the objects of promoting the manufacture of surgical and dental instruments and of placing these industries on a sound economic basis. Questionaries have been sent to a number of manufacturers; any others who would like to assist with information should communicate with the secretary, Surgical and Dental Instrument Panel, room 507, Portland House, Tothill Street, London, S.W.1.

A Course at Cambridge

A fortnight's general refresher course will be held at Ad brooke's Hospital, beginning on Oct. 14. This cours open to medical officers released from the Forces, and National Health Insurance practitioners who will receive same allowances as are paid to doctors released from Services. Application should be made to Dr. A. C. D. F Trinity Hall, Cambridge. (Tel. 5047.)

Airborne Medical Society

A permanent Airborne Medical Society is being for whose membership will be open to all medical and de officers who have been entitled to wear the maroon be Further information may be had from the hon. secret Mr. Guy Rigby-Jones, M.C., F.R.C.S.E., 63A, Belsize Pa Gardens, London, N.W.3.

Franco-Anglo-American Medical Society

The third quarterly meeting of this society will be held 11, Chandos Street, London, W.1, on Tuesday, Sept. at 2.30 P.M.; when Lord Horder will take the chair.

Ministry of Health

Mr. H. Symon has been appointed under-secretary in the ministry, and Miss Enid Russell-Smith as under-secretary in the health services division.

Dr. J. D. ROBERTSON, of the Courtauld institute of th Middlesex Hospital, is shortly leaving for the United Sta where he will lecture for the University of California a San Francisco and Los Angeles and will deliver a Ma Foundation lecture at Rochester, Minn.

Medical Diary

AUGUST 25 TO 31

Thursday, 29th

EDINBURGH POSTGRADUATE LECTURES
4.30 P.M. (Royal Infirmary.) Dr. J. D. S. Cameron: Treatm of Amœbiasis.

Appointments

CLARKE, H. OSMOND, M.B. Dubl., F.R.C.S.: surgeon to the Lo Hospital, and asst. director of the orthopædic and acc dept.
DAVIDSON, J. ROMANES, M.D. Edin.: medical superintend Orphan Homes of Scotland and Colony for Epileptics, Bri of Weir, Renfrewshire.
HANNESSON, HANNES, M.R.C.S.: medical superintendent, Croyd County Borough Sanatorium, North Cheam, Surrey.
KERSHAW, J. D., M.D. Lond., D.P.H.: M.O.H. and school M. Colchester, Essex.

Hospital for Sick Children, Great Ormond Street, London:
- ASERMAN, DAVID, M.D. Camb., D.A.: anæsthetist.
- BLAIR, L. G., M.R.C.S., D.M.R.E.: director, dept. of radiolo
- CREAK, E. MILDRED, M.D. Lond., M.R.C.P., D.P.M.: phys dept. of psychological medicine.
- EVANS, PHILIP, M.D. Manc., F.R.C.P.: physician to outpati
- HENRY, T. C., M.R.C.S., L.D.S.: dental surgeon.
- KIERNANDER, F. B., M.B. Lond., M.R.C.P., D.M.R.E., D.PHYS.M: director, dept. of physical medicine.
- LUCAS, B. G. B., M.R.C.S., D.A.: anæsthetist.

Colonial Service:
- AUSTIN, T. A., L.R.C.P.I., D.T.M. & H., D.P.H.: D.M.S., Ugan
- BASSETT, Captain T. H., M.B. Lond.: M.O., Tanganyika.
- BOSSMAN, J. E., L.R.C.P.: M.O., Gold Coast.
- BRODIE, ALISON G., M.B. Aberd.: M.O., *Malaya*.
- CAUCHI, F. J., M.D. Malta: M.O., Nigeria.
- CLARK, Major J., M.B., D.P.H.: M.O., Nigeria.
- DAVIES, Captain A. G. M., M.B. Brist.: M.O., Tanganyika.
- DAVIES, H. N., M.B. Edin., D.T.M.: medical specialist, Tangan
- DRYDEN, S., M.B.: asst. M.O., Jamaica.
- DUNNETT, Major A. H., M.B. Aberd.: M.O., Gold Coast.
- DYKES, W. S., M.B. Glasg.: M.O., Malaya.
- ELBERT, J. J., M.B.E., M.B. Glasg.: M.O., Nigeria.
- FITTON, J. M., M.B. Leeds, F.R.C.S.: orthopædic surg Mauritius.
- FRAZER, Major S. M., M.R.C.S.: M.O., Bermuda.
- GORDON, S. G., L.R.C.P.: M.O., Gambia.
- HOUSTON, Captain G. F., M.R.C.S.: M.O., Nigeria.
- JACKSON, Major G. C. A., M.B. Lond.: M.O., Northern Rhode
- McGARITY, J. F., M.B.: M.O., Malaya.
- THOMPSON, Captain D. E., M.B. Camb.: M.O., Tanganyika.
- TIMMIS, W. G., M.B. Lpool: M.O., Uganda.
- UPTON, Flight-Lieutenant B. H. B., M.B. Birm.: M.O., Fiji.
- VAN SOMEREN, Lieut.-Colonel R. K. A., F.R.C.S.E.: M.O., Ken
- WILLETT, K. C., M.R.C.S.: trypanosomiasis officer, Tanganyi
- WRIGHT, Captain R.: M.O., Nyasaland.

Examining Factory Surgeons:
- JOBSON, C. F., M.R.C.S.: Trowbridge, Wilts.
- LLOYD, D. H., M.R.C.S.: Carmarthen.
- MAIN, B. CAMPDEN, M.R.C.S.: Earl's Colne, Essex.
- ROSS, M. S., M.B. Edin., F.R.C.S.E.: Hemsworth, Yorks.

terrified valetudinarians. So perhaps for the present it may be wise for us to continue to tell our rheumatic cardiacs that they have indeed got a murmur, but that there is no need for them on that account to consider themselves invalids.

We try, therefore, not to miss early valvular heart disease, and we spend a lot of time teaching its importance to students. But we are so morbidly afraid of over-oking its presence that we often commit the worse ror of diagnosing heart disease when none exists. The ung man with a functional systolic murmur, who gives history of ten days' "rheumatism" in childhood, whose other died of some vague "heart trouble," and who ows an inverted T-wave in the third lead of his electro-rdiogram, is almost certain to be diagnosed sometime having rheumatic heart disease, though he probably is perfectly normal healthy individual. Such a diagnosis ay have a devastating effect upon a suggestible youth, ading to a cardiac neurosis which may result in a life f useless semi-invalidism. Such an error is at least as reat as that of failing to detect a carcinoma in a man of ixty. Nowadays, with so much emphasis on the preven-ive aspect of medicine and the early diagnosis of ymptomless disease, there is a danger that we may orget the reverse of the coin—the perils of the erroneous iagnosis of disease-less symptoms. Let us not, in voiding the scylla of the overlooked cancer, fall into the harybdis of the medically-induced ‡ neurosis. The first nay be fatal to life, the second fatal to happiness.

CHOICE OF DRUGS

Consideration of drug therapy at once brings to mind a profusion of myths. A few drugs are of proved and nassailable value, and their mode of action established. Some are useful, and their mode of action may be partly understood. Many are almost certainly worthless, and their mode of action mythical. Yet all have their ardent advocates; and to question the traditional pharmaceutical rites is to raise a storm of unprofitable controversy. Some of the more useless preparations should be pensioned off into honourable obscurity, while others should be partially retired. Glucose, for example, will always have its deserved place in therapeutics, but its value and importance have been greatly overestimated. Many physicians do not seem to appreciate that the sole advantage of glucose over other forms of sugar, when given by mouth, is that it is less sweet and can thus be taken in larger quantities without producing nausea. It is commonly believed that by giving a monosaccharide all ready for absorption, a favour is conferred on the alimentary tract; whereas the digestive apparatus, however ill its owner, is quite capable of producing the same end-result with no trouble, and with none of the additional expense. Furthermore, the indiscriminate employment of glucose in all varieties of hepatic disorder is quite pointless. The origin of this custom, and of many other similar therapeutic traditions, is the ignorant misapplication to human beings of quasi-scientific animal experiments. It is a practice unfortunately on the increase as the habit of bedside observation declines and the reverence for non-clinical research grows. There is but one criterion of the value of any therapeutic procedure: does it, however attractive in theory or successful with guineapigs, really work with patients?

It would be wearisome to recount in detail all the many traditional customs in therapeutics whose rationale is most dubious, and whose practical value is negligible. Some have been mentioned already. The prescription of massage and exercises, without diet, as a means of reducing obesity; the faith in milk as a food suitable for every patient and almost every disease, though large numbers of adults loathe it; the routine swathing in cotton-wool of the chests of perspiring pneumonia patients, "lest they catch cold"—these and many other methods of treatment are based on theorising from inadequate experimental data, on the ancient error of arguing from the particular to the general, or on no apparent rational thought-process at all. Too few physicians take the trouble to ask themselves if such methods are of any real value in practice. John Hunter said all this many years ago in three words: "Don't think; try." The object of this polemic is to sow the seeds of doubts—healthy, constructive, scientific, doubts. We do so many things in medicine from traditional custom, handed down to us by our teachers when we were students and copied unthinkingly from one textbook to another. We are so used to doing them that we seldom stop to think whether our actions are dictated by reason or by superstition. If we do, we probably comfort ourselves by reflecting that they must be of some value, or they would not be so widely practised or so long-lived. That this assumption is entirely unjustified is shown by the many similar faiths, such as leeching and blistering, which survived and were universally practised for centuries, and yet have now been totally discarded.

A traditional custom may be very valuable. Many empirical procedures have later been shown to have a sound scientific basis. To refuse to employ a method of treatment of proved practical value because its rationale is as yet obscure is foolishly narrow-minded. But it behoves us to keep our practice of medicine in constant repair; to drag out the old customs from the cellar from time to time, and to examine them critically in the light of day. One will be found to be still useful, and to produce good results even if its modus operandi be not yet fully understood. Another will be revealed as a mere mumpsimus, and fit only for the dustbin.

PSYCHONEUROSIS

A final word on a modern myth which is rapidly being established. "Anxiety state" or "anxiety neurosis," applied indiscriminately as a label to all sorts of psychological upsets, is today the successor of the older "neurasthenia" as a species of diagnostic portmanteau. An anxiety state is a definite emotional condition, and its presence or absence is determined by a simple question: does the patient manifest anxiety? If not, then whatever psychological ailment he may have, it is not an anxiety state. The unjustifiably widespread use of the term is due, in large measure, to an unnecessary feeling of compulsion on the part of the physician to give the patient a diagnostic label. This passion for pigeon-holing is nowhere more ill-directed than in psychological medicine. Disordered emotions are peculiarly individual, and defy the procrustean diagnostic method. The result of such glib labelling is merely to confuse the ætiological issue, and to hinder a clear understanding of the principles of treatment.

In recent years there has grown up a commendable awareness of the importance and ubiquity of psychological factors in disease. Psychology and psychiatry are no longer the poor relations of medicine. But before we non-experts label a patient anxiety state, obsessional neurosis, hysteria, or (fashionable nowadays) psychosomatic disorder, let us be quite sure that we know what we mean by these terms, and whether we are justified in using one of them in any particular instance. Otherwise their true and precise meaning will become perverted, and we shall have opened up a new chapter in the mythology of medicine.

I am indebted to Dr. W. N. Mann and to Dr. M. A. Partridge for valuable suggestions and merciless criticism of this paper.

---

‡ A more elegant, though unfamiliar, epithet is "iatrogenic" (ἰατρός = physician; γένεσις = creation).

is soothing to the harassed physician, in despair of an excuse for interference in a disease which has no proved remedy. It is true that in many cases mild prohibitions in the matter of diet do no harm, and satisfy the patient's demand for action on the part of his medical adviser. But let us *not thereby be led into believing that our diets* have necessarily done any good, and arrogate to ourselves credit which properly belongs to the *vis medicatrix naturæ*. It is permissible sometimes to practise harmless deception on our patients for their own good: it is never permissible to deceive ourselves.

These remarks apply with almost equal force to the use of tobacco and alcohol. Do we, when we lightly forbid these amiable vices in our older patients, give enough thought to how we are depriving them of much-needed solace in their declining years, and adding to the winter *of their discontent*? When "use" becomes "abuse" it is a different question, and most of the controversy rages round the dividing line between the two. The moral aspect still further confuses the issue. But to forbid smoking and drinking to our patients without substantial reason if not cruel is useless, because in nine cases out of ten we shall not be obeyed.

The forced overfeeding of patients with normal appetites, such as was formerly practised on consumptives, is as foolish as underfeeding. The custom is waning, but its place threatens to be filled by the habit of indiscriminate exhibition of vitamins. There can be few patients with "neuritis" who have not received large but futile doses of aneurine, and not many with chronic skin diseases who have not swallowed ascorbic acid ad nauseam, all to little or no purpose. The mythical healing properties attributed to vitamins by now far exceed their very real ones.

TRADITION IN NURSING

In the field of nursing care the traditional custom is very strong. That this is in part due to the essential conservativeness of women is likely, but most of the blame must rest upon ourselves, because, as Cohen (1946) has pointed out, we fail to keep our nursing staffs informed of recent advances in therapeutics. It would be tedious to detail all the innumerable small traditional superstitions that are sedulously observed in every hospital and nursing-home. It is hardly credible that, until the blitz swept it away, it was the invariable custom in one of the major London teaching hospitals to close the operating-theatre after a death on the table (from whatever cause), in order to carry out a semi-religious rite of complete cleansing and fumigation. By this means, presumably, evil spirits were driven out and the soul of the departed exorcised. In most medical wards the patient with acute rheumatism or acute nephritis is invariably deprived of sheets and nursed between blankets, whatever the state of his sweat glands. One has only to remove the sheets from one's own bed on a warm night to appreciate the tickling discomfort that this procedure entails. The acute rheumatic or diphtheria patient is further harassed by being compelled to lie flat on his back in bed with one pillow, or even with none at all—a posture sometimes psychologically desirable for and fairly well tolerated by children, but one of considerable discomfort for adults. Decubitus in disease should be determined primarily by the patient's comfort and not by vague theorising on the part of his physician. Again, if our patient requires an enema, it will still be compounded of soap, turpentine, treacle, ox-bile, or some such rectal irritant, though the complete efficacy of normal saline was proved *long ago*.

It is our shame that we are often so ignorant of nursing methods that we are unaware of the existence of these and other outmoded manœuvres; or, worse still, we dismiss them, with a shrug and a tolerant smile, as harmless fads. Admittedly they are not lethal practices. But they cause needless discomfort to patients or cre purposeless work for nurses, and should be tactfully firmly discouraged, even in the teeth of hostile wa sisters.

The undesirability of overlong immobilisation of ol patients has, in recent years, become more wid appreciated. The dangers of venous thrombosis and passive pulmonary congestion, and the difficulties re-mobilising stiffened joints and muscles, today le physicians to get their patients with, say, corona thrombosis up and about earlier than they used to. younger people, however, the risks of prolonged decubit are perhaps not so fully realised, because they are psych logical rather than physical. Sometimes such und prolongation arises from the mistaken belief that "normal" temperature, of not more than 99° F, is essential preliminary to the patient's getting up. As t *British Medical Journal* recently (1946) pointed o temperatures of 100° F or even more are occasiona compatible with perfect health, particularly if the patie be of tense, nervous temperament. Granted that su "pyrexia," especially during convalescence from a illness, should call for careful exclusion of lingerin organic disease; but if a reasonable search has been mad and has proved negative, and if the patient has n complaints, it is surely wiser to let him get up (when th "*pyrexia*" will *often* subside) than *to* keep him in be indefinitely. Yet the latter practice is by no mean uncommon, despite the possible harm to a suggestibl adolescent, through sowing the seed of a persisten hypochondria in later life.

ATTACHING A LABEL

A similar common and harmful error is to diagno anæmia in children or young adults when no su condition exists. Anæmia is a definite disorder, whi can be identified, if present, by a simple blood-cou The indiscriminate use of the term to disguise ignoran of the true cause of the patient's complaints, and t *prolonged* and *useless dosing* with *iron* and liver th follows, cannot be too strongly deprecated. The ad lescent girl who is pale, who will not eat, and who fain easily, is in all probability working too hard at school an pining with unrequited love for her form-mistress. Bland pills will not cure her. But in later life all her littl hypochondriacal ailments and psychological upsets m be firmly attributed by her to "anæmia as a child."

All this arises from our exaggerated fear of overlook organic disease. We have all had it drummed into us students that to miss an early carcinoma is an unpardo able error. So it is. But what we often fail to real is the profound psychological harm we may do diagnosing organic disease where none exists. Nowhe is this more clearly shown than in the field of hea disease. We congratulate ourselves when we de the early mitral diastolic murmur in the symptomle young woman about to have her first baby. Yet sometimes wonders whether it really matters very mu With symptomless rheumatic heart disease, do we fact succeed, by all our fussing and frowning on ov exertion, in prolonging life or, more important, enhancing its enjoyment? Would not such patients happier and probably live just as long (provided th were not engaged in some freakishly strenuous occupatio if they remained in blissful ignorance of their steno valve and fibrosed myocardium till the day when ignorance was no longer possible? We do not, if we wise, inform our symptomless hypertensives of the st of their blood-pressure. Should we not apply the sa rule to our rheumatic-heart patients? Unfortunatel there is a snag. If we do not tell them ourselves, soon or later someone else will. And he may do so in th wrong way, suggesting to them, *perhaps, that they* on the brink of death, and thereby turning them in rified valetudinarians. So perhaps for the present may be wise for us to continue to tell our rheumatic rdiacs that they have indeed got a murmur, but that ere is no need for them on that account to consider emselves invalids.

We try, therefore, not to miss early valvular heart sease, and we spend a lot of time teaching its importance students. But we are so morbidly afraid of overoking its presence that we often commit the worse ror of diagnosing heart disease when none exists. The oung man with a functional systolic murmur, who gives history of ten days' "rheumatism" in childhood, whose other died of some vague "heart trouble," and who ows an inverted T-wave in the third lead of his electroardiogram, is almost certain to be diagnosed sometime s having rheumatic heart disease, though he probably is perfectly normal healthy individual. Such a diagnosis ay have a devastating effect upon a suggestible youth, ading to a cardiac neurosis which may result in a life f useless semi-invalidism. Such an error is at least as reat as that of failing to detect a carcinoma in a man of ixty. Nowadays, with so much emphasis on the preventive aspect of medicine and the early diagnosis of ymptomless disease, there is a danger that we may orget the reverse of the coin—the perils of the erroneous iagnosis of disease-less symptoms. Let us not, in voiding the scylla of the overlooked cancer, fall into the harybdis of the medically-induced[‡] neurosis. The first may be fatal to life, the second fatal to happiness.

CHOICE OF DRUGS

Consideration of drug therapy at once brings to mind a profusion of myths. A few drugs are of proved and unassailable value, and their mode of action established. Some are useful, and their mode of action may be partly understood. Many are almost certainly worthless, and their mode of action mythical. Yet all have their ardent advocates; and to question the traditional pharmaceutical rites is to raise a storm of unprofitable controversy. Some of the more useless preparations should be pensioned off into honourable obscurity, while others should be partially retired. Glucose, for example, will always have its deserved place in therapeutics, but its value and importance have been greatly overestimated. Many physicians do not seem to appreciate that the sole advantage of glucose over other forms of sugar, when given by mouth, is that it is less sweet and can thus be taken in larger quantities without producing nausea. It is commonly believed that by giving a monosaccharide all ready for absorption, a favour is conferred on the alimentary tract; whereas the digestive apparatus, however ill its owner, is quite capable of producing the same end-result with no trouble, and with none of the additional expense. Furthermore, the indiscriminate employment of glucose in all varieties of hepatic disorder is quite pointless. The origin of this custom, and of many other similar therapeutic traditions, is the ignorant misapplication to human beings of quasi-scientific animal experiments. It is a practice unfortunately on the increase as the habit of bedside observation declines and the reverence for non-clinical research grows. There is but one criterion of the value of any therapeutic procedure: does it, however attractive in theory or successful with guineapigs, really work with patients?

It would be wearisome to recount in detail all the many traditional customs in therapeutics whose rationale is most dubious, and whose practical value is negligible. Some have been mentioned already. The prescription of massage and exercises, without diet, as a means of reducing obesity; the faith in milk as a food suitable for every patient and almost every disease, though large numbers of adults loathe it; the routine swathing in cotton-wool of the chests of perspiring pneumonia patients, "lest they catch cold"—these and many other methods of treatment are based on theorising from inadequate experimental data, on the ancient error of arguing from the particular to the general, or on no apparent rational thought-process at all. Too few physicians take the trouble to ask themselves if such methods are of any real value in practice. John Hunter said all this many years ago in three words: "Don't think; try." The object of this polemic is to sow the seeds of doubts—healthy, constructive, scientific, doubts. We do so many things in medicine from traditional custom, handed down to us by our teachers when we were students and copied unthinkingly from one textbook to another. We are so used to doing them that we seldom stop to think whether our actions are dictated by reason or by superstition. If we do, we probably comfort ourselves by reflecting that they must be of some value, or they would not be so widely practised or so long-lived. That this assumption is entirely unjustified is shown by the many similar faiths, such as leeching and blistering, which survived and were universally practised for centuries, and yet have now been totally discarded.

A traditional custom may be very valuable. Many empirical procedures have later been shown to have a sound scientific basis. To refuse to employ a method of treatment of proved practical value because its rationale is as yet obscure is foolishly narrow-minded. But it behoves us to keep our practice of medicine in constant repair; to drag out the old customs from the cellar from time to time, and to examine them critically in the light of day. One will be found to be still useful, and to produce good results even if its modus operandi be not yet fully understood. Another will be revealed as a mere mumpsimus, and fit only for the dustbin.

PSYCHONEUROSIS

A final word on a modern myth which is rapidly being established. "Anxiety state" or "anxiety neurosis," applied indiscriminately as a label to all sorts of psychological upsets, is today the successor of the older "neurasthenia" as a species of diagnostic portmanteau. An anxiety state is a definite emotional condition, and its presence or absence is determined by a simple question: does the patient manifest anxiety? If not, then whatever psychological ailment he may have, it is not an anxiety state. The unjustifiably widespread use of the term is due, in large measure, to an unnecessary feeling of compulsion on the part of the physician to give the patient a diagnostic label. This passion for pigeon-holing is nowhere more ill-directed than in psychological medicine. Disordered emotions are peculiarly individual, and defy the procrustean diagnostic method. The result of such glib labelling is merely to confuse the ætiological issue, and to hinder a clear understanding of the principles of treatment.

In recent years there has grown up a commendable awareness of the importance and ubiquity of psychological factors in disease. Psychology and psychiatry are no longer the poor relations of medicine. But before we non-experts label a patient anxiety state, obsessional neurosis, hysteria, or (fashionable nowadays) psychosomatic disorder, let us be quite sure that we know what we mean by these terms, and whether we are justified in using one of them in any particular instance. Otherwise their true and precise meaning will become perverted, and we shall have opened up a new chapter in the mythology of medicine.

I am indebted to Dr. W. N. Mann and to Dr. M. A. Partridge for valuable suggestions and merciless criticism of this paper.

MEDICAL PHOTOGRAPHY

A REVIEW

PETER HANSELL
M.R.C.S., A.R.P.S.
From the Department of Medical Photography, Westminster Hospital, London

THE application of photography to medicine is by no means new; in line with the development of other applications, photography has been used as a recording medium in the practice of medicine since very early days. Indeed, the fact that books on photomicrography appeared as early as 1872 might serve as a rebuke to us today; for, though there have been advances, these have been quite sporadic, and still the subject lacks coördination and integration. In this respect we have much to learn from the advances made in other countries, notably the United States of America. A consideration of the quality of American work has tended to make many workers in this country critical of their own methods, and this in turn has led to the realisation that medical photography can no longer be done in a backstair cupboard.

To meet the requirements of complicated modern techniques, a veritable photographic laboratory is necessary, and there must be opportunity for photographic, besides medical, research. It is probably the appreciation of the scope of a modern department which has led to the abandonment of the older term "clinical photography," for its bedside implications were somewhat limiting.

Whereas photography was first introduced into hospitals and teaching institutions as a recording medium, this function has now become somewhat subservient. With the development of the epidiascope and other projectors, the tendency today is to regard photography as the means whereby knowledge may be disseminated in a visual form. Obviously, routine records must form a valuable source of such material, but the development of visual methods of education and the tremendous impetus given to this subject by the recent war need no elaboration here. This tendency is substantiated by the appearance of articles in the current journals on the subject of medical films; and, though we must welcome the display of such an interest, it would be as well to bear in mind that it has grown up totally without relationship to the development of medical photography as a whole; it therefore does not conform to a set plan, and is a trifle premature.

The establishment of a new hospital department prompted an investigation of the field, so that benefit might be derived from the experience of other workers. So far this survey has been confined to the main teaching hospitals in the London area. It has been slow and is by no means complete, for at the outset a major difficulty was experienced—that of tracing workers engaged in medical photography. Once this difficulty had been partially overcome, discussions on the subject of staff, training, salaries, equipment, and techniques were possible. The resultant information, though limited, is not without interest, and already many obstacles in the path of better medical photography have become apparent. The aim here, therefore, is to review and present some of the common difficulties, in the hope that they will be of value to those interested in advancing the subject.

ACCOMMODATION

Lack of suitable accommodation is perhaps the greatest single drawback to the natural development of a hospital photographic department, to say nothing of the demoralising effect which such conditions have on the people who work therein. Work in cramped staff quarters soon becomes a drudge, even if initial enthusiasm is enough to withstand such inconveniences. Few enough members of hospital committees are conversant with the processes which go to make a finished photograph, and hence are quite unaware of the intensely tiring effect of working in an ill-ventilated dark-room. The idea that any old cupboard was good enough in the pioneer days seems to have remained unchanged by the passage of time. Against this, one is, however, painfully aware of the cramped conditions in which most hospital workers have found themselves in the last few years, but in these days of planning and rebuilding it is as well to remember that, for the photographic staff to enjoy any degree of comfort, at least four rooms are essential—two dark-rooms and two small studios, one of the latter being set aside for special techniques such as photomicrography, X-ray reduction, copying of documents, and so on.

EQUIPMENT

Hand in hand with accommodation goes the consideration of equipment; only here both funds and accommodation are limiting factors. Experience has shown that medical photographers are extremely resourceful people; further, they are willing to suffer inconvenience caused by the absence of an elaborate piece of equipment—such difficulties are classically surmounted by the judicious use of plasticine and string. With the hospital carpenter as an ally, many efficient contrivances have been evolved, though the ideas have rarely been disseminated.

This state of affairs raises several interesting points. It would be interesting to know, for instance, if such resourcefulness is a necessary quality of a medical photographer, or whether it has merely been inbred through years of vain striving for more apparatus. Furthermore, it has in the past been difficult for the

edical photographer to publish his ideas, even had he she so desired—the photographic and medical press ve offered little space for such a limited subject. nally, in this connexion, attention should be drawn to e fact that most hospitals are reluctant to spend what ems to them to be vast quantities of money on photo-aphic apparatus. Often they will not be convinced that otographic equipment depreciates but little if carefully ndled, and is therefore to be regarded more as a pital investment. Where the swing of the pendulum s been in the other direction, and a department boasts hundreds of pounds' worth of equipment, a careful rutiny will often reveal the fact that such expenditure as undertaken in a fit of aberration, and that little or o attention has been paid to basic requirements: the test American endoscopic camera may be found, but an ccurate exposure meter is deemed unnecessary.

FILING

In the light of these somewhat limited investigations, owever, there seem to be one or two common failings, nd one or two lines which, were they exploited, would ad to the setting up of a much more efficient and useful ervice. Deserving of special mention in this respect is he question of filing systems, for at the outset one can e dogmatic and state that, where the products of a nedical photographic department are to be used in onnexion with teaching, any money expended on filing ystems forms the most solid single investment. So mportant is this question that a more detailed considera-ion is merited. Broadly speaking, three distinct types f request may be made of the photographic department t any time: (1) for work to be executed—the patient's ame, hospital index number, and diagnosis may or may ot be supplied; (2) for reprints or duplicates of work one in the past, when the same information, though ften of doubtful accuracy, may be to hand; and (3) for eprints or reproductions of all work executed in the ast three or four years on such and such a disease. It is this latter type of request which is of paramount impor-ance to the teacher or author, and yet which renders seless all but the most comprehensive filing systems.

Clearly then, a most rigorous cross-check must be kept on such information as patient's name, index number, disease, photographic data, and filing number. Besides which, it may not be realised that copyright laws are applicable in a limited sense, so that a record should be kept of the name of the attendant physician or surgeon. This point need not be laboured, for it is obviously desirable from an ethical standpoint. The recording of these details does not involve as much office work as might be supposed; a system which has been found to work in practice has as its foundation the request form, a printed card with spaces for data on both sides, and measuring 6 in. by 4 in. to fit a standard card-index cabinet (fig. 1). Apart from the initial annoyance attendant on the birth of any new form, full cooperation from the hospital staff may reasonably be expected.

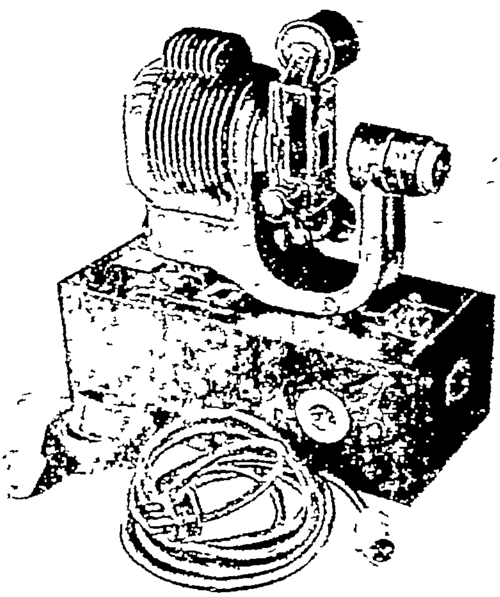

Fig. 2—A filmstrip projector.

In parallel with this, the necessity of a subject-index catalogue or file has been mentioned. If teaching material is to be always ready to hand, it would seem reasonable to keep duplicate prints of all work executed, so that these may be permanently available for inspection and can, in the course of time, indicate deficiencies in the complete recording of cases. If this idea should be rejected on the grounds of the additional expense involved—though it should be remembered that filing copies need only be small—it is essential to compile some classified manuscript record to achieve the same objects, if only in part.

At the risk of appearing tedious, the office work has been emphasised because experience has shown it to be the weakest link in the chain which extends from doctor to photographic department, and from photographic department to teacher or author. Only too often has one seen good photographic records descend into the dusty basement with discarded case-histories, and, as counterparts, the unclassified negatives on the shelves of the photographic department.

FILMSTRIP

A new medium which has recently been launched in all its splendour on the educational world is the 35-mm. filmstrip. This particular medium has been in existence since the acceptance of the 35-mm. miniature camera,

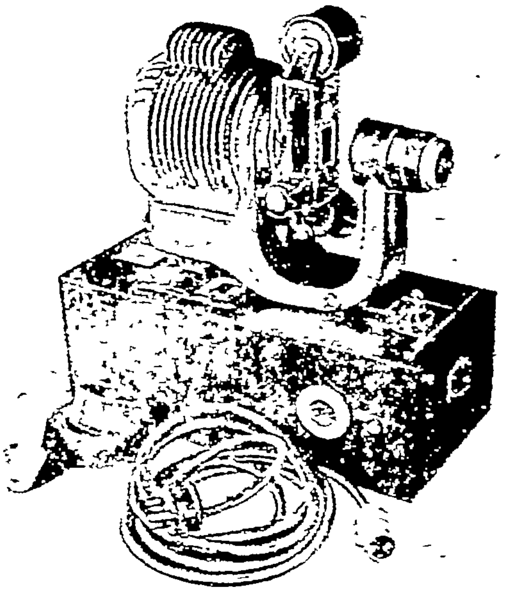

Fig. 2—A filmstrip projector.

In parallel with this, the necessity of a subject-index catalogue or file has been mentioned. If teaching material is to be always ready to hand, it would seem reasonable to keep duplicate prints of all work executed, so that these may be permanently available for inspection and can, in the course of time, indicate deficiencies in the complete recording of cases. If this idea should be rejected on the grounds of the additional expense involved—though it should be remembered that filing copies need only be small—it is essential to compile some classified manuscript record to achieve the same objects, if only in part.

At the risk of appearing tedious, the office work has been emphasised because experience has shown it to be the weakest link in the chain which extends from doctor to photographic department, and from photographic department to teacher or author. Only too often has one seen good photographic records descend into the dusty basement with discarded case-histories, and, as counterparts, the unclassified negatives on the shelves of the photographic department.

FILMSTRIP

A new medium which has recently been launched in all its splendour on the educational world is the 35-mm. filmstrip. This particular medium has been in existence since the acceptance of the 35-mm. miniature camera,

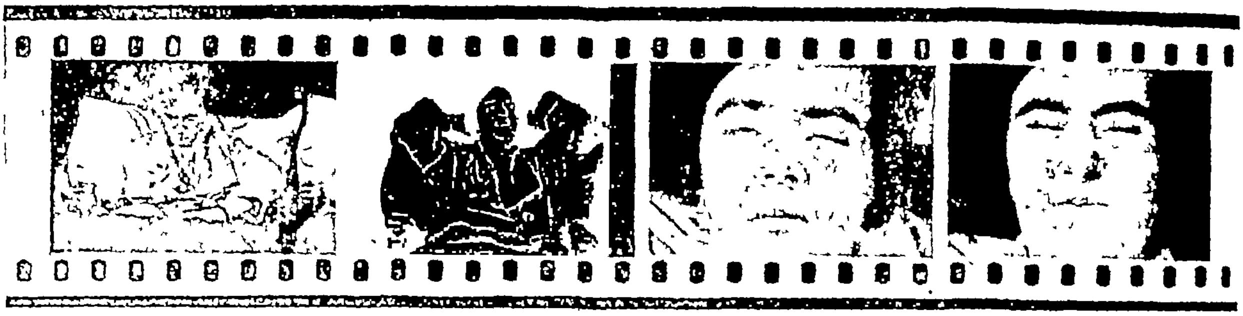

Fig. 3—Four frames from a typical 35-mm. filmstrip, showing patient with myasthenia gravis before and after injection of 'Prostigmin.'

but it is the war years which have been responsible for its development—today there are numerous commercial firms in existence whose sole purpose it is to produce filmstrips of a high order, and even these are still in their infancy, for it was demands made from the Services which were largely responsible for their creation.

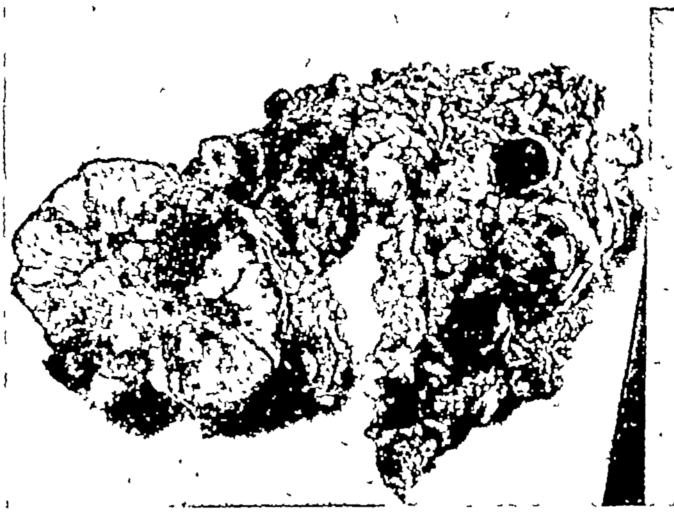
Up to now, filmstrip does not seem to have found a place in medical education, despite its great potentialities which have been proved in part. As has already been intimated, there is nothing new or mysterious about this medium; users of miniature cameras have been accustomed to making little rolls of transparencies for projection purposes, these constituting the crudest filmstrips. In the strictest sense of the term, a filmstrip is a roll of standard 35-mm. positive film, on which is printed a series of pictures, radiograms, or diagrams in a definite sequence, with a view to presenting a logical story of the subject in question; when such a strip is intended for individual viewing, and is not accompanied by a verbal commentary, the necessary labels and subcaptions may be included in the frame.

It must be admitted that a higher standard of workmanship is necessary to produce blemish-free miniature pictures, whether in strip or slide form, than in the case of lantern-slides (3¼ in. sq.), but still the method has much to commend it. Standard lantern-slides are heavy, bulky, fragile, and expensive, whereas filmstrip is free from these factors, which tend to impede a more general use. Filmstrip is cheap to produce; it is small in bulk and light to carry, a roll of 40 pictures being lighter and smaller than a single standard lantern-slide. One objection which might be raised is the fact that the order of the pictures or frames has necessarily to be predetermined; but, if such a strip is prepared to a script, this should not present a real difficulty. In any case, when the negatives have been produced, they may be printed in any order, or, alternatively, the strip may be divided into its composite frames, which are then mounted as miniature lantern-slides.

Filmstrip projectors are very small and compact, and may easily be carried from room to room as the need arises. Their construction is such that a darkened room, though advisable, is by no means essential. As a further suggestion, such filmstrips could, after being used for lectures, be filed in a library with suitable notes, so that students might at any time view them with an individual reader. It would be as well, therefore, for medical photographers to watch the development of the filmstrip industry and familiarise themselves with the techniques involved in their production, and so apply this comparatively new medium to their own uses in the near future (see figs. 2 and 3).

DISPLAY

As has been indicated throughout this article, the scope of hospital photographic departments has been



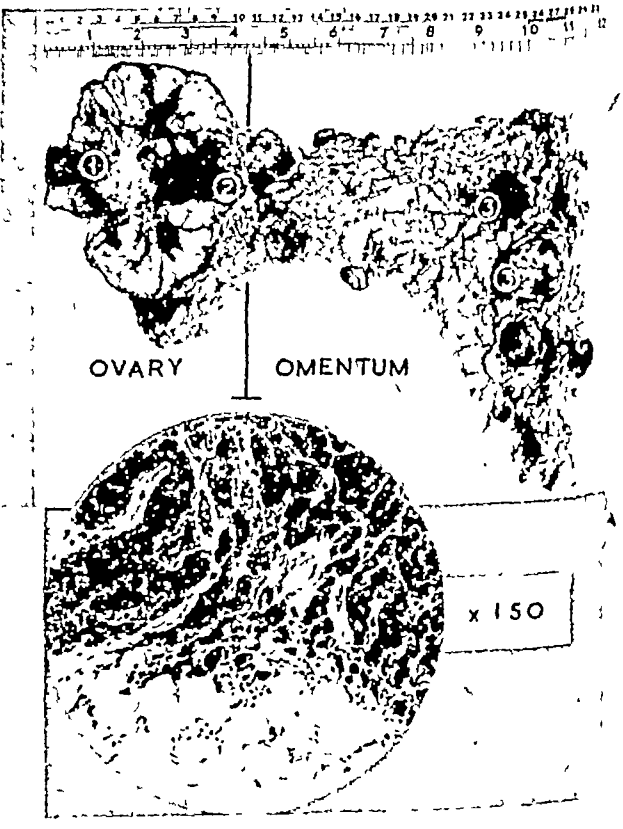


Fig. 4—Operation specimen of ovary and attached omentum: (a) a bad but conventional photograph; (b) same specimen showing its size and morbid histology; (1) metastatic carcinoma completely taking the place of ovarian tissue; (2) hæmorrhagic areas; (3) secondary nodules in omentum.

remely limited up to now. Little or no use has been le of display. Static displays of photographs and rbid specimens with appended notes can be of isiderable value to the student. They form an easily imilable source of information; and, with a little operation from the curator of the hospital museum, would be possible to arrange for such displays to changed at regular intervals. In this manner it possible, for instance, to present a complete record of a rticular case, whether rare or common, from the time patient first attends, through the results of special vestigations, to the logical conclusion, whether this the necropsy room or a return to normal.

To facilitate this type of presentation, it is obviously advantage to have the services of an artist, for the ntinuity between stages is not always at first apparent, it can more readily be made so by the inclusion of mple keys and diagrams. A visit to any exhibition of ientific photography will convince even the most eptical that medical photographers are, and can be, sourceful enough to produce displays independently. he fact remains, however, that the place for these isplays is in the medical school, and not so much in the chibition hall.

MORBID SPECIMENS

While on this subject, we might digress for a moment consider the age-old problem of the photography of iorbid specimens. Such photographs obviously play n important part in displays of the type outlined above, nd yet how often do we see such a photograph of this ature which conveys any real information? As students, we must all have experienced our teachers showing hotographs of specimens which they had actually seen r removed, and yet which, without such a preview, onveyed no information save that of a tangled mass of emains. It is true that the photography of morbid pecimens is not without some difficult aspects, but how nuch more valuable such a record becomes if a little are is exercised in the final presentation. The inclusion f arrows, labels, and scales requires very little extra rouble, and makes all the difference between a good and bad record (fig. 4*a* and *b*).

MEDICAL PHOTOGRAPHERS

We have now traced the story and shortcomings of medical photography to date, but what of the future? Many hospitals are seeking to establish new departments; but even if they have the equipment and the accommodation, how are these departments to be staffed? And what inducements are there for people to take up medical photography as a career?

Many men and women leaving the Forces are attracted by hospital work, but, having decided that they would like to undertake training in the subject, find it difficult to progress beyond this decision. There is no room in this specialised field for a person without a good photographic training, and institutions which provide courses of instruction in pure photography are already booked to capacity. A further difficulty is that there are no set standards up to which a medical photographer shall be trained, either in terms of medical or photographic knowledge, and no examinations exist to test their final proficiency in the subject. One or two commercial firms run short training courses of instruction, but prospective participants are faced with the danger of a particular commercial bias being instilled into them during the course of their training; and, even so, it is doubtful if such courses are complete enough to prove of lasting value.

It is probable that the Institute of British Photographers will, in the near future, devote a section of their final examination to the subject of medical photography; indeed, such a step would be highly desirable. But, if the standards of this examination demand a lengthy and complete training, as they should, it is doubtful if people would be persuaded to undertake long and expensive training when, at the end of it, they would receive only mediocre salaries.

The medical photographer is essentially highly skilled and is expected to be conversant with more techniques than he would be in any other branch of photography. It is reasonable, therefore, to suppose that his remuneration should be at least on the same level as that of a photographer employed commercially.

The whole problem is, however, a vicious circle, since hospitals, quite rightly, do not expect to pay high salaries to semi-skilled workers; and, in the absence of the standards alluded to, it is difficult to decide on the degree of skill achieved at any one time in the course of an apprenticeship.

In addition to these purely academic considerations, one notes with interest that the Royal Photographic Society has recently set up a medical group which should be of interest to all medical photographers and doctors interested in photography. It is to be hoped that, with this backing, many instructive meetings may be held which will permit a healthy interchange of ideas among workers in this field. But such a state of affairs can only be achieved if the group receives all the support it deserves.

One can only conclude, therefore, on a note of hope: that the post-war years will see standards of training laid down for medical photographers, and the establishment of training courses comparable with those open to workers in the United States, and that the achievement of these desiderata will be reflected in the quality of medical illustrations in the future.

SUMMARY

A brief review of medical photography up to the present day is given.

A few of the main difficulties encountered in a recent incomplete survey of the field are mentioned.

Filmstrip as a comparatively new teaching medium is described and illustrated, and its application to medical education is emphasised.

The necessity for training courses and training standards is briefly discussed, and present facilities are mentioned.

THE HOSPITAL PHOTOGRAPHIC DEPARTMENT

BRIAN STANFORD
M.R.C.S., D.M.R., F.R.P.S.

THE principles of photography, long conducted empirically, are now firmly established on a scientific basis. Parallel with this transformation has been the development of a scientific application of photographic technique: the camera is now used both as an accurate recording instrument and as an instrument of research. These developments, though potentially of great value to medical science, have not yet penetrated into our practice, which still presents a huge unexplored field for applied photography.

This paper outlines the functions and requirements of a clinical photographic department which exploits fully all the potentialities that photography can offer medicine. It is appreciated that the proposals are too ambitious for immediate realisation in full, but departments can be set up now within the framework outlined, and built up steadily until all these possibilities are realised.

Photographs which recall to individual memory a particular condition are no longer adequate records for a clinic with constantly changing personnel. Photographs must provide an absolute image to the mind of a doctor who has never seen the patients before; they must even provide an absolute image to a doctor who has never seen a similar complaint before. Photographs must provide an accurate basis for measurement: the orthopædic clinic desires more accurate evidence of returning mobility in a stiff joint than is provided by a variable protractor resting on soft tissue; the cancer clinic desires more accurate evidence of alteration in size of a lesion than is provided by a ruler bridged across an area of indefinite edge. Photographs must provide an accurate record of change in subjective appearance: the psychiatric clinic desires regular portraits to show change in facial expressions; the hormone clinic desires regular records of bodily configuration to show effect of treatment; the welfare department desires portraits to show return of a healthy glow to the cheeks of a convalescent. Photographs must provide accurate evidence to the laboratory worker, whose researches may extend over several generations of experimental animals with a short life-span. The list is endless.

STANDARDISATION

All this can easily be achieved with suitable equipment, careful work, and recognised standardising techniques. The aim of any clinical photographic department must be to produce, after an interval of hours, days, or years, a record of a condition which is indistinguishable from the first in every respect—except that the lesion itself has changed. But standardisation of this kind, that is to say repeatability of conditions, is not sufficient of itself. *It is equally important that, given two lesions,* whether of the same nature or not, occupying the same relative position on two different individuals, the two records are identical except for the clinical differences they portray. Such a state of affairs demands an even greater degree of standardisation; for, besides the duplication of conditions required by the first example, we now require to have laid down standard techniques for photographing different areas of the body.

These techniques will therefore have to stipulate: (1) the angle of view at which the camera is pointing in relation to the area of the body presented; (2) the distance of the camera; (3) the disposition of the lights in the same way; (4) the nature of the lighting; (5) the colour-to-monochrome distortion convention (or the colour error introduced); and (6) the contrast convention. These requirements can be met by recording angles and distances accurately; noting the type of light-source and reflector used; including in the field of view a rule, a neutral grey-scale, and a colour-chart; and controlled developing and printing which produces, as a matter of routine, prints with matched grey-scales.

Furthermore, one view will not be sufficient; each standardised technique will demand at least two views, lighting conditions or colour-to-monochrome distortions to provide a basis for differential evaluation; and one or more of these views may be a stereoscopic pair. The grey-scales, rule, and colour-scale will be included on every print. This is not to suggest that a special view may not also be desirable; it often will be, but the standard views must also be presented in every case.

These may seem extravagant requirements, but comparable conditions are accepted practice in radiology. Every fracture is recorded from two or more angles under standardised conditions of angulation and distortion scale (anode-film distance), stereoscopic pairs are often asked for, foreign bodies are sought by taking radiographs at two different penetrations, and so on. There are, in fact, many large volumes devoted to radiographic standardising techniques.

But out of all this emerges a principle new to clinical photography. Once standardised techniques are accepted for certain areas, and once the doctors who use the records have become accustomed to the conventions, they will have achieved a state comparable to that to which they are accustomed in radiology. The records, read in conjunction and against a background of experience of records made in an identical manner, will have a meaning of their own; these records will, in fact, evoke a real image in the mind of a person who has not yet seen the condition they record. When that state of affairs is reached, photography will have become a useful adjunct to medicine.

VALID TEACHING MATERIAL

It is clear that in time sufficient material will accrue from the activities outlined above to provide pictorial examples of most clinical conditions. Moreover, since the students will have been educated to recognise the conventions adopted in these standardising techniques, they can be presented with records of conditions of which they have never seen the like and still derive a real image from them. This is a greater consideration than many experienced teachers can realise; they are prone to present as an illustration of a condition a record which successfully reminds them of the case it represents but is meaningless to the student. But the hospital photographic department will not stop there. It will make, for teaching purposes, records with a different emphasis.

For example, standardised records of a direct, an indirect, and a femoral hernia will be of value in each patient's notes, but for teaching purposes each will have to be presented alongside the other corrected in this instance not to original scale but reduced or magnified so that the pubic-spine to iliac-crest distance is identical on the paper on all three records.

Again, for clinical purposes still photographs will be taken more often than cinematograph, and slides will rarely be needed; but, for teaching students, many films, slides, and filmstrips, will be specially made.

he medical staff. It will prepare teaching material quest; for this purpose an extensive cross-reference system will be maintained. It will have direct s to the wards, and record, with the consent of the or in charge, such conditions as are needed to increase reference section, besides conditions of which it es experience to evolve new standardising techniques. hermore, it will constantly evolve new recording niques for record and research in conjunction with other departments.

time this department will have achieved sufficient rience to justify its taking in students of clinical tography, and so increase not only the internal iency of its hospital but also the range of public ices provided by that hospital.

ORGANISATION

taff.—The director will be medically qualified but osen for his photographic knowledge and experience. will be under his guidance that the department proves s usefulness, and a man with untried ideas will be of reater worth than one who wishes to practise currently cognised techniques.

The assistant director, who will possess a degree in hysics or chemistry, will also be selected for his photographic knowledge and experience. He will bring to he department a more precise scientific outlook than oes the medical director, and contribute to the general esearch activities of the department the knowledge in hich he has qualified.

The two photographers will be trained nurses. They will possess a keen interest in photography, but may be aught detailed technique during the early activity of the department. They must be carefully selected in the full ealisation that in a few years they will leave the department and found a new one elsewhere.

A microscopist will be a qualified fellow of the Institute of Medical Laboratory Technicians with special experience of histology and bacteriology. He will be given an additional training in photomicrography such as is given by, for instance, the Royal College of Science and Technology, and will be expected to contribute advances to photomicrographic technique.

Though much of the routine photographic procedure will be undertaken by all the members of the staff, a dark-room technician will relieve them of excessive routine duties and ensure continuity of output.

A secretary will control the requests, maintain the files, and attend to disposal of the records made.

A cineradiography technician, a qualified radiographer, will be given special instruction in photographic techniques and will be maintained by this department jointly with the diagnostic radiology department.

An instrument mechanic, capable of making fine optical instruments from rough designs, will be essential to the progress of the department. He will require first-class equipment, and may possibly be shared with the radiotherapy or the clinical pathology development departments.

A nurse and a porter will be attached in their professional capacities to the department.

Some members of the staff here outlined will be difficult to obtain, for a department such as is described will be unique to begin with. There is no doubt, however, that the right persons will be attracted to the posts, for the steady development of the specialised appointment of hospital physicist shows that people do exist ready to apply knowledge of one field to another, with great benefit to both. In selecting personnel there need be no discrimination of sex for any of the posts. The guiding principle will be the selection of people with tact and a kindly outlook; for, though experience shows that patients are usually fully coöperative, yet sensitive people exist who feel that in some way they are being laughed at if a photograph is asked for; the photographic department must never give cause for this suspicion to have good ground.

Premises.—As much work as possible will be done in the department itself, where centralised facilities are available and the necessity for moving much apparatus is minimised. The main studio will be at least 40 ft. × 20 ft., with the ceiling not less than 15 ft. high. Three subsidiary studios, one for standardising portrait apparatus, one for standardising full-length views, will be 10 ft. × 15 ft., with ceilings 10 ft. high: and three small studios for small objects or pathological specimens will be 10 ft. × 8 ft.

Several dark-rooms and accessory rooms will be needed:

(1) The *chemical mixing room,* 6 ft. × 8 ft., will be fitted with two sinks, shelves, cupboards, and bins, next door to (2) the *chemical store-room* which opens onto an outside service yard; next door, but with no interconnecting door, is (3) the *sensitised material store-room,* built to comply with nitrate fire-risk regulations, and also opening onto the yard as well as into the department; (4) a *dry dark-room* for loading sensitised material into holders and cassettes; (5) the main *wet dark-room (negative),* equipped for developing all kinds of plates, films, and cine-films; (6) the main *wet dark-room (prints)* equipped with contact-printers and enlargers along one wall, and developing-dishes and sinks along the opposite wall; and (7) the *drying-room* containing drying-cupboards and racks for negatives and cine-film, and drying and glazing machines for prints, as well as print-trimmers. This will lead directly through to the secretary's office. Space must also be allocated to a copying-bench, a cine-titling bench, a cine-editing bench, and possibly micro-filming and photostat apparatus.

A secretary's office, filing-room, and directors' office will be needed. Dressing-cubicles for the patients, linen-cupboard, lavatories, and store-rooms for miscellaneous equipment will be needed, as well as a small surgery where the surface of lesions, if not already prepared in the ward, may be cleaned and redressed under proper conditions after photography.

Equipment.—A detailed inventory of equipment would be out of place here, for each department will find its own needs, but a minimal scale can be indicated for the chief items.

Studio Cameras.—A whole-plate studio-type with range of lenses and smaller-size plate adaptors; a quarter-plate studio-type with range of lenses; a quarter-plate reflex; and a Leica-type with range of lenses. A 16-mm. cine for general purposes.

Other cameras: copying camera; micro-filming and filmstrip camera; Leica-type for endoscopy; 16-mm. cine for micrography and endoscopy: and various cameras attached to the different standardising setups, and the cineradiographic camera.

Enlargers: whole-plate; quarter-plate; Leica-type.

Projectors: $4^1/_4$ in. × $4^1/_4$ in. slide; 50 mm. × 50 mm. slide: filmstrip; 16-mm. cine (silent); 16-mm. cine (sound); "movieola."

Lights: two 2-kW, four 1-kW, two 500-W variable spotlights ("moles"); two 2-kW floods; overhead batten in large studio; two condenser-discharge ("kodatrons"); miscellaneous photophloods.

Miscellaneous equipment: drying-cabinets, glazing-machines, and the like have already been mentioned. To these must be added a transmission-reflection densitometer, scales, and so on: and (in the studios) backcloths, tripods, a dolly, &c.

Specialised equipment: the department will design and build for itself gantries for photographing the bedridden, equipment for recording in the operating-theatres, and the like. The standardising equipment will be based on the X-ray diagnostic sinus-stand and over-table apparatus, supplemented by special additions.

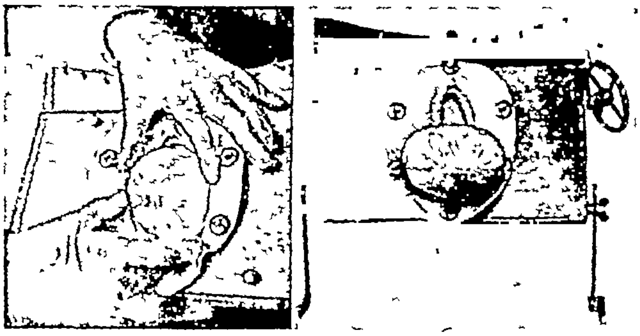
Such, in outline, are the likely requirements of a department equipped to meet all the demands likely to be made of it, and to progress with its independent schemes for advancement of technique. This scale of premises, staff, and equipment will not be required immediately the department opens, but it will need all this and probably more within three years of establishment.

ANATOMICAL MODELS IN TEACHING

RAOUL DE SEIGNEUX, M.D.
PROFESSOR OF OBSTETRICS, UNIVERSITY OF GENEVA

MODELS reproducing the appearance, consistence, and feel of body tissues can contribute much to medical teaching, not only by sparing patients unnecessary examinations but also by giving the student a wider experience than he would otherwise get. With this in mind, I developed some years ago a technique for making models from gelatin on a gauze base; the colouring is mixed with the material, which resists extremes of temperature. The models are supple but unbreakable.

Models made in this way have been used successfully in the teaching of obstetrics. A model of a full-term fœtus was made and a manikin devised to which interchangeable parts could be fixed. A series of models reproduce successive stages of labour with the os in various stages of dilatation. By means of a simple lever at the side of the manikin (fig. *b*), all the movements of the fœtal head in labour can be reproduced. The effects of alternating uterine contraction and relaxation are simulated; and delivery at the vulva can be practised (fig. *a*). The material takes stitches well, and models have been constructed to enable students to practise stitching of the various layers of the pelvic floor. A collection of interchangeable models has been built up to represent various gynæcological disorders: the position and the feel are the same as in the human subject, but the accuracy of the sensory impression and its interpretation can be checked by removing the part representing the abdominal wall. Some models have been arranged to give practice in the lesser gynæcological operations, such as dilatation of the cervix, curettage, replacement of a displaced uterus, and the fitting of a pessary.



(*a*) (*b*)

Models for use in obstetrical teaching: (*a*) delivery of the fœtal head; (*b*) external rotation of the head, showing wheel for controlling the movements of the fœtus.

By the same method the complete muscular system of an entire body, with nerves and blood-vessels, has been reproduced. The different layers of any region can be represented, layer by layer, on successive models. A model of head and thorax has been built for laryngoscopic examinations, and by squeezing a bulb the vocal cords can be made to vibrate as in life. Affections of the tongue, tonsils, pharynx, and upper respiratory tract can be accurately portrayed with interchangeable parts. Complete limbs have been reproduced for practice in setting fractures; a model of the lower urinary tract provides experience in catheterisation, and, again by the use of interchangeable parts, in the identification of pathological states of the bladder.

I have demonstrated my collection of models before various congresses of the Association of French-speaking Gynæcologists and Obstetricians—at Geneva in 1923, in Paris in 1925, at Lyons in 1927, and at Bordeaux in 1931, and have received a multitude of inquiries from universities as far distant as Helsinki, Sydney, Melbourne, Dunedin, and Manila, showing that the models satisfy a real need in medical teaching.

CHILDREN WHO SPEND TOO LONG IN BED

J. A. MCCLUSKIE
M.B., B.Sc. Glasg.
CHILD PSYCHIATRIST, SURREY AND SOUTHEND EDUCATION COMMITTEES

NOTHING could be farther from an accurate opinion of sleep and its control than the idea, prevalent among doctors as well as laymen, that so long as we have plenty of sleep we are all right. The doctor will advise extra sleep during an illness or in convalescence, but will not tell the parents to discontinue the extra sleep when the child is well. As a result, the parents often institute permanently the early-to-bed habit which, with its helpmate early-to-rise, is undoubtedly one of the golden rules of life. But they omit the early rising, so poor Johnny has to adapt himself to an extra hour in bed which he does not need. Months afterwards he appears before the psychiatrist because he is talking or restless in his sleep, and the story is that the illness caused it.

Directions for feeding in the most meticulous detail are known to mothers through a galaxy of pamphlets, books, leaflets, and dried-milk tins such as no civilisation has probably ever known. Sleep requires the same detailed directions, yet even medical textbooks almost ignore the subject.

Children of different ages react in different ways to being expected to sleep too long:

(1) *Infants* protest violently by crying vigorously if they are not lifted, and into this group fall most of those babies whose mothers maintain that it is better to let them cry. If a baby has an hour too much sleep during the day it will certainly cry during the night. But the crying will be put down to feeding aberrations, certainly by the parents and probably by the doctor too.

(2) *Toddlers* show restlessness, crying, and head-banging, and may develop other pastimes, such as thumb sucking, masturbation, and bed-wetting.

(3) *Children of school age* acquire such symptoms as talking in their sleep, sleep-walking, and bed-wetting.

RULES FOR SLEEP

Babies.—All mothers should know the hours of sleep required by their babies at each month. As the age increases the sleep should decrease, not according to whim but according to plan. In the crying baby, tests for oversleeping should receive as much weight as inquiry into deficiency in diet. This plan should be calculated as follows:

Age (months)	*Sleep required (hours)*	
Up to 1	.. 24	except for feeding
,, 2	.. 21	
,, 3	.. 20	
,, 4	.. 19	
,, 5	.. 12	+3 in morning and 3 in afternoon
,, 6	.. 12	
,, 7	.. 12	+2½ ,, ,, 2½ ,,
,, 8	.. 12	
,, 9	.. 12	+2 ,, ,, 2 ,,
,, 10	.. 12	+1½ ,, ,, 1½ ,,
,, 11	.. 12	+3
,, 12	.. 12	+2½

Every baby will require his own slight modification of this plan by, say, about 30 *minutes* according to his idiosyncrasy, but the lay-out should remain. For example, at five months it is necessary to calculate the sleep on a basis of 12 hours' continuous sleep during the night with the variations in the day sleep. Should the child of six months sleep for, say, 13 continuous night hours then the greatest care should be taken to deduct an hour from the 6 hours allowed for the day sleep. If the 12 hours' night sleep is held as the permanent s and the day sleep is varied, each child as he develops soon give his mother an indication of how much day p he requires. But this is certain: variation by even 30 minutes from the amount of sleep each particular d requires at each month produces violent change of aviour. The most placid infant deprived of an hour's p can become a veritable little screaming cat. Consely—and this is not so generally recognised—if a ld of eight months is given the sleep due to a child six months he certainly will have his parents walking midnight carpet. And how easy it is for a tired ther to allow her child to oversleep.

Toddlers.—Hours of sleep for toddlers should be culated as follows:

At 2 years old	..	12 hours	+1 hour in daytime
,, 3 ,, ,,	..	12 ,,	
,, 4 ,, ,,	..	11½ ,,	

Two years is a very difficult age for sleep regulation, cause the amount of sleep required is about 13 hours. e child often sleeps more than its nocturnal 12 hours, ich reduces the day sleep due to him to less than one ur. His mother, on the other hand, expects him to on sleeping during the day. Indeed one otherwise ite good little booklet advises that "the long morning ep" should go on until school age. If this is done, e child will certainly cut down his night sleep by aking during the night.

In toddlers who are getting too much sleep headnging is common. I read in a popular ladies' journal cently a request to the "Aunt Jane" column for lvice on this subject. Little Gwendoline was waking uring the night and "driving my husband almost antic"; it seemed to have been forgotten that the ddler was the one who was being driven frantic in the rst instance. The superficial reason in most of these sleep" deviations is in almost every instance the versleeping of the child. The parents do not know that definite scientific programme of gradual sleep modifiation is necessary, because they have never been given ne.

A serious situation is created by keeping very young hildren, say, aged 3 years, from getting up in the orning because they have awakened too early. A ealthy child of this age wakens with the dynamic force f an animal and the vocal exuberance of a bird. Many hildren are treated with the most appalling dictatorial yranny by their parents because of this; force and xuberance are sapped, and the child lies in his bed neek, cowed, and completely inhibited, earning from is forceful mother the name of now being a very good oy, but later he becomes the easy victim of the aggressive hild in the playground and of difficult rising in later ife.

In one doctor's house in which I lived for a short time a little boy, aged 3 years, lay from 6 A.M. until 8 A.M. in a wet bed playing with the blankets. His mother boasted that he was at one time very difficult on waking, but she had trained him to lie quietly.

School-children.—Hours of sleep for children of school age should be:

At 5, 6, 7 years old	.. .. ..	11 hours
,, 8, 9, 10 ,, ,,	.. .. ..	10½ ,,
,, 11, 12, 13 ,, ,,	.. .. ..	10 ,,

Many children do adapt themselves to over-protective parents by doing something, such as reading for an hour or so either before going to sleep or even on waking early in the morning. But many children cannot, or are not allowed to, adopt such a practice, and then the evil begins: masturbation or brooding is substituted for reading.

Another deviation is that the child falls asleep when he first goes to bed but later develops a light sleep during which he manifests the talking and restlessness already mentioned. In these cases there is almost always some other form of conflict, such as the association of an aggressive child with an aggressive parent, but the precipitating cause is the hour too long in bed. In other cases he cannot sleep when he goes to bed, and so later falls into a very deep sleep and possibly wets the bed or is tired in the morning.

Here are two examples:

CASE 1.—A boy, aged 14, about whom the assistant medical officer's report stated: "Referred by his headmaster for failure to concentrate and nail-biting. At home he is some days very amenable, and other days he is most aggravating. Very excitable and temperamental. Excessive finger-biting first started with air-raids in 1940. Failure to concentrate—takes a long time to go to sleep. Has taken money on two occasions some years ago but no trouble recently."

The notable feature of this report is the "dash" and small "t" for "takes" in the sentence "Failure to concentrate—takes a long time to go to sleep." No wonder he was unable to concentrate, because he was going to bed at 8 P.M. and getting up at 8 A.M.

CASE 2.—A girl, aged 6 years, was restless in school, talking in her sleep, and waking "too early" in the morning. She went to bed at 6.30 P.M. and got up at 7.45 A.M. on the instructions of her mother. At 2 years of age she used to be awake 2 hours during the night until her mother gave her a smack, and immediately she went to sleep.

The obvious psychiatric points are the expression "waking too early in the morning" and the fact that the mother's smack coincided with the end of the period of wakefulness.

On children of school age some parents are exerting alarming discipline. Boys of 9 and 10 years and even boys bursting with energy on the threshold of puberty are compelled to spend from 8 P.M. till 8 A.M. in bed while the parents boast of their carefulness in this matter. How it is going to be possible to educate the parents I cannot say.

Prof. Charlotte Bühler observes:

> "There is a fundamental law of development at work. . . . The development is especially clear in the diminishing needs of sleep for the child. In the course of the first year most parents who are at all concerned with the child pay special attention to its sleep. Later this interest is not so general." [1]

Her figures are not in my opinion consistent: the observation that children of 10 months slept for eleven hours while children of 12 months slept for thirteen hours calls for further research. My own figures for infants tending toward the maximum are actually higher than hers. The times she quotes as "minimum for children and adolescents" are supported by foreign authors and correspond to my own, but they are much too indefinite at ages 1 to 3 to be of practical use.

Boarding-schools and remand homes show uniformity in treatment of the 9–13 group, although remand-home boys seem to manage with less sleep than those in boarding-schools. Mothers should take a lesson from all these institutions. There are considerable variations among the schools in the younger age-groups, with a tendency to bed the youngest at what I consider too early an hour.

The very excessive bedding indulged in by parents is not found in schools, however; and, in any case, community life is not so likely to encourage egocentric or introspective living. For this reason, to allow for individual idiosyncrasies, boarding-schools should add about half an hour to the times recommended above.

I am indebted to the headmasters of Eton College, and St. Christopher's School, Letchworth, for helpful observations.

---

JOSEPH ROGERS PRIZE.—The president of the Royal College of Physicians and the master of the Society of Apothecaries of London have awarded this prize for 1946 to Dr. R. C. Wofinden, of Greasborough, Rotherham.

Reviews of Books

Illustrations of Regional Anatomy

(6th ed.) E. B. JAMIESON, M.D., senior demonstrator and lecturer emeritus, anatomy department, University of Edinburgh. Edinburgh: E. & S. Livingstone. Pp. 320. 75s.

THE wide and continuous demand for Dr. Jamieson's book of anatomical diagrams has led to a new edition. The pictures are mostly based on blackboard diagrams, originally built up, step by step, to explain the relations of the parts. The shapes of the parts are therefore shown with a sharpness of outline which may sometimes tantalise the student who finds the grey structures which he dissects very different from the purple or green ones here outlined. Learning from diagrams has the further danger that they may mislead by oversimplification. But no student who understands the functions of art would be so foolish as to suppose that these brilliant illustrations represent the reality which he will find in the body. And when he leaves the obscurities of the tissue which he finds in the dissecting-room he will be refreshed by the clarity of Dr. Jamieson's polychromatic analysis.

In the interest of Scotch exactness we must take exception to the legend of fig. 37. Surely the visual pathway in the brain should not be called "the path of conduction of light."

The Management of Obstetric Difficulties

(3rd ed.) PAUL TITUS, M.D., obstetrician and gynæcologist to the St. Margaret Memorial Hospital, Pittsburgh. London: H. Kimpton. Pp. 1000. 50s.

AN author generally believes, and always hopes, that each succeeding edition of his book is an improvement. In this respect Dr. Paul Titus can have no doubts, for, good as were the first two editions, the third surpasses them. The subject of sterility is now brought up to date and the chapter on X-ray pelvimetry has been rewritten. An account is given of the technique of caudal analgesia; the extraperitoneal method of cæsarean section is described; and the chapter on intravenous infusions has been completely revised, with consideration of Rh incompatibilities and erythroblastosis. Though the chapter on puerperal sepsis may still merit amplification, the work as a whole is well balanced. Each chapter may be regarded as a monograph on its subject and is followed by an adequate bibliography. Illustrations are well chosen, well drawn, and well reproduced, including eight coloured plates. The author's enthusiasm for his work is, unconsciously perhaps, imparted to the reader. The introduction contains a lengthy and critical review of the practice of obstetrics of today, which will be of value to those considering the problem in this country.

Manson's Tropical Diseases

(12th ed.) SIR PHILIP MANSON-BAHR, C.M.G., D.S.O., M.D. Camb., F.R.C.P., senior physician to the Hospital for Tropical Diseases, London, the Albert Dock Hospital, and the Tilbury Hospital; consulting physician to the Colonial Office. London: Cassell. Pp. 1068. 42s.

IN the 12th edition of this standard English work the section on the typhus group of fevers has been rewritten, and that on leprosy has been largely modified. Sundry figures in the text, particularly in the chapters on parasitology, have been redrawn, and the total number has been increased, while the number of plates has been slightly reduced. A chapter on the technique of injection and of blood-transfusion has been inserted. Another valuable addition is a table of the drugs employed in the treatment of tropical diseases, which indicates the structural formula of each compound, its dosage and method of administration, and the occasion for its use, with some comments on its therapeutic properties and value where these are in doubt. The material in the chapters on medical entomology has been redrafted and rearranged, with manifest improvement. All the additional information has been included without increasing the bulk of the volume, which has in fact fewer pages than its predecessor.

This edition is an up-to-date and comprehensive compendium, which well meets the present need for information on tropical diseases, whether encountered at home or overseas.

Mitchell-Nelson Textbook of Pediatrics

(4th ed.) Editor: WALDO E. NELSON, M.D., professor of pædiatrics, Temple University. London: W. B. Saunders. Pp. 1350. 50s.

THOUGH completely rewritten this work retains something of the tradition of the previous editions, through the close association of the present editor with the late Dr. Mitchell. It is an outstanding production: indeed we know of no single-volume pædiatric textbook which equals it in scope. The inclusion of a wide selection of key references is one of the features which made earlier editions so valuable to the pædiatrician. Professor Nelson has been faced with the inevitable difficulties of grouping diseases according to age-incidence, infective or other nature, and systems, but has steered his way with remarkable success. The book starts with a survey of pædiatrics, followed by a section on the care and evaluation of well children which is useful and well balanced except perhaps for the part on "mental and emotional development" which is relatively short and gives the impression of being superficial. Otherwise there is little to criticise and much to commend. Recent advances are dealt with faithfully but not at disproportionate length, and those who have been out of touch with pædiatrics during the war will, if they secure this volume for their shelves, be able to face with confidence a world resounding with words like rhesus factor and toxoplasmosis.

Government in Public Health

HARRY S. MUSTARD, B.S., M.D., LL.D., De Lamar professor of public health practice and director, School of Public Health, Columbia University, New York. London: Oxford University Press. Pp. 219. 8s. 6d.

IN 1942 the New York Academy of Medicine appointed a committee to study how to make available to the whole country the most efficient practice in preventive and curative medicine "at a lower per capita cost than the present system permits." The committee early felt the need of systematic data. The present volume, the second of twelve, describes the development of public health in the United States, and points out the directions in which further development is most needed. It is a valuable book, objective and critical. Professor Mustard shows not only where but why attempts at progress have met with success or failure. As he writes with tomorrow in view, he deals more with shortcomings than achievements, holding that future improvements "will not be attained by gloating over past accomplishments"; and instead of laying stress on the high standard of public health work that prevails over large areas in America he is more concerned to point out that "the local authorities of at least one-fourth of the population of the United States have so far failed to provide their citizens with anything approaching adequate health service." He concludes that what is most urgently necessary is to deal effectively with that situation. Written with a light touch, his book is not only informative and suggestive but remarkably entertaining.

Manual of Surgical Anatomy

(Pocket edition.) Prepared under the auspices of the committee on surgery of the Division of Medical Sciences of the National Research Council by TOM JONES, professor of medical and dental illustration and head of department of illustration studios, University of Illinois; W. C. SHEPARD, art editor, W. B. Saunders Company. London: W. B. Saunders. Pp. 254, 15s.; and pp. 195, 2

THIS manual has two almost equal parts. The first is an atlas including many drawings illustrating the anatomy of operative surgery. The second is an explanatory index. The drawings are excellent, but some have suffered by condensation in size for the pocket edition, and the book is somewhat marred by a number of anatomical and printer's errors. Also, though the terminology adopted in the atlas is predominantly that of the B.N.A., it is not consistently so. It seems rather curious that, when 7 pages are devoted to the surgery of the sympathetic, there is not a single illustration of the surgical approach to the spleen. Nevertheless the drawings of operative surgery are particularly well done, and though the manual cannot be recommended to students it should find a place in postgraduate surgery.

TREATMENT OF ANÆMIA

with

COLLIRON

(colloidal iron hydroxide)

Colliron provides iron in a palatable and assimilable form for the treatment of iron deficiency anæmias and for supplementing dietary intake, particularly in invalids, expectant and nursing mothers.

Colliron is colloidal iron hydroxide with copper, cobalt and manganese. Each drachm contains the equivalent of 6 gr. of metallic iron or 32 gr. Ferri et Ammonii Citras.

Issued in bottles of 4, 8, 40 and 80 fl. oz.

Colliron capsules containing iron, nicotinic acid
and aneurine hydrochloride are also available.
Issued in bottles containing 30 and 250 capsules.

BOOKS FOR THE STUDENT

NEW (SEVENTH) EDITION — THIRTIETH THOUSAND

With 1063 Illustrations (203 coloured) — Demy 8vo — 40s. net

A SHORT PRACTICE OF SURGERY

By **HAMILTON BAILEY,** F.R.C.S., Surgeon, Royal Northern Hospital, London and **R. J. McNEILL LOVE,** M.S., F.R.C.S. Surgeon, Royal Northern Hospital, London

KETTLE'S PATHOLOGY OF TUMOURS

By **E. H. KETTLE,** M.D., B.S. Revised and rewritten by W. G. BARNARD, F.R.C.P., and A. H. T. ROBB-SMITH, M.A., M.D. Third Edition. Fully Illustrated. Demy 8vo. **21s.** net; postage 9d.

CARDIOVASCULAR DISEASE IN GENERAL PRACTICE

By **TERENCE EAST,** M.A., D.M. Oxon., F.R.C.P. Lond. Second Edition. With 48 Illustrations. Demy 8vo. **12s. 6d.** net; postage 7d.

THE ACTION OF MUSCLES

Including Muscle Rest and Muscle Re-education

By **Sir COLIN MACKENZIE,** M.D., F.R.C.S., F.R.S.Edin. Second Edition. Biographical Note by C. V. MACKAY, M.D. Melb., with a portrait. With 100 Illustrations. Demy 8vo. **12s. 6d.** net; postage 7d.

COMMON SKIN DISEASES

By **A. C. ROXBURGH,** M.D., F.R.C.P. Seventh Edition. With 8 Coloured Plates and 184 Illustrations in the Text. Demy 8vo. **18s.** net; postage 7d.

A HANDBOOK OF RADIOGRAPHY

By **J. A. ROSS,** M.A. Camb., M.R.C.S. Eng., L.R.C.P. Lond., D.M.R.E. Liverp. Second Edition. With Illustrations. Demy 8vo. **10s. 6d.** net; postage 7d.

NOTABLE NAMES IN MEDICINE AND SURGERY

By **HAMILTON BAILEY,** F.R.C.S., and **W. J. BISHOP,** F.L.A. Second Edition. Profusely Illustrated. **15s.** net; postage 6d.

Just published — Third Edition — With Illustrations (some coloured) — Royal 8vo — 50s. net

PRACTICAL HANDBOOK OF THE PATHOLOGY OF THE SKIN

An Introduction to the Histology, Pathology, Bacteriology and Mycology of the Skin with Special Reference to Technique.

By **J. M. H. MACLEOD,** M.A., M.D., F.R.C.P. Lond., Physician and Hon. Director of the Pathological Department, St. John's Hospital, etc., and **I. MUENDE,** M.R.C.P. Lond., M.B., B.Sc. Lond., Pathologist with Outpatient Clinic and Lecturer in Pathology to St. John's Hospital; Dermatologist to the Middlesex County Council, Willesden General Hospital, etc.

REGIONAL ANALGESIA

By **H. W. L. MOLESWORTH,** F.R.C.S. Eng. Second Edition. With Illustrations. Demy 8vo. **8s. 6d.** net; postage 7d.

ANATOMY AND PHYSIOLOGY FOR NURSES

By **J. L. HAMILTON PATERSON,** M.D. Lond., M.B., B.S., M.R.C.P., M.R.C.S. Demy 8vo. **9s.** net; postage 7d.

A GUIDE TO HUMAN PARASITOLOGY

For Medical Practitioners

By **D. B. BLACKLOCK,** M.D. Edin., D.P.H. Lond., D.T.M. Liverp., and **T. SOUTHWELL,** D.Sc., Ph.D. Fourth Edition. With 2 Coloured Plates and 122 Text Illustrations. Royal 8vo. **15s.** net; postage 9d.

THE SULPHONAMIDES IN THEORY AND PRACTICE

By **J. STEWART LAWRENCE,** M.D. Edin., M.B., Ch.B., M.R.C.P. Demy 8vo. **9s.** net; postage 6d.

THE THEORY AND PRACTICE OF MASSAGE AND MEDICAL GYMNASTICS

By **BEATRICE M. GOODALL-COPESTAKE.** Sixth Edition, revised. With 129 Illustrations. Demy 8vo. **16s.** net; postage 7d.

THEORY AND PRACTICE OF NURSING

By **M. A. GULLAN,** formerly Sister Tutor of St. Thomas's, London. Fifth Edition. With Illustrations. Demy 8vo. **12s. 6d.** net; postage 7d.

A HANDBOOK OF SANITARY LAW

For the Use of Candidates for Public Health Qualifications

By **B. BURNETT HAM,** M.D., D.P.H. Camb. Twelfth Edition. F'cap 8vo. **7s. 6d.** net; postage 5d.

THE SYMPTOMATIC DIAGNOSIS AND TREATMENT OF GYNÆCOLOGICAL DISORDERS

By **M. MOORE WHITE,** M.D. Lond., M.B., B.S., F.R.C.S. Eng., M.R.C.O.G. Second Edition. With 107 Illustrations. **16s.** net; postage 6d.

MINOR SURGERY

By **R. J. McNEILL LOVE,** M.S., F.R.C.S. Second Edition. With numerous Illustrations. **15s.** net; postage 6d.

By the Same Author

A GUIDE TO THE SURGICAL PAPER

With Questions and Answers

Second Edition. F'cap 8vo. **6s.** net; postage 3d.

VARICOSE VEINS, HÆMORRHOIDS AND OTHER CONDITIONS

Their Treatment by Injection

By **R. ROWDEN FOOTE,** M.R.C.S., L.R.C.P., D.R.C.O.G. Demy 8vo. With 54 Illustrations. **12s. 6d.** net; postage 4d.

BIOLOGY STAINING SCHEDULES

For First-Year Students

By **R. R. FOWELL,** M.Sc. Second Edition. Paper Covers. **2s.** net; postage 2d.

WHAT TO DO IN CASES OF POISONING

By **W. MURRELL,** M.D. Fifteenth Edition. Revised by H. G. BROADBRIDGE, M.B., B.S., M.R.C.S., L.R.C.P. F'cap 8vo. **8s.** net; postage 4d.

SANITARY LAW IN QUESTION AND ANSWER

For the Use of Students of Public Health

By **C. PORTER,** M.D., B.Sc., M.O.H., and **JAMES FENTON,** M.D., D.P.H. Fourth Edition. Crown 8vo. **10s.** net; postage 7d.

This Year, Next Year

In the past year we have been thinking much about the new National Health Service, but little about the medical schools which must provide the men and women to staff it. The tasks before these schools are vast. They must repair the losses of war: new buildings planned in 1939 are still unbuilt, and many of the old buildings, besides suffering the natural process of decay, have been damaged. And they lack teachers: men who would normally have been trained for teaching and research work in the ancillary sciences, such as biochemistry, physiology, pharmacology, and pathology, have instead become much-needed clinicians.

The schools themselves have long recognised that they should be taking more students, and planning their curriculum to fulfil modern demands. The Goodenough report emphasised this duty, and the National Health Service, bringing with it a growing demand for doctors, makes it urgent. Moreover, the schools must, at least for several years, try to meet the claims of an abnormally large number of candidates for medical training, many of them ex-Servicemen. The exact number of candidates is unknown, since often they apply simultaneously to two or more schools, but they certainly far exceed the schools' capacity. How long the heavy demand will be maintained is unknown; but some see it as a wave subsiding slowly over the next few years The coming academic year, following twelve months of mass demobilisation, will probably carry the peak; but the following year may almost equal it, because the demobilised, though fewer, will be younger, and therefore the readier to seek a university training. In 1948–49 the ranks may be swollen by the return from the Forces of the many schoolboys whose claims have been deferred this year to leave the way clear for ex-Servicemen.

INTAKE AND SELECTION

Wherever possible, the schools have responded to the present surge by increasing their intake; but though they regret the need to reject candidates who would normally be accepted, they have set their face against taking so many that the standard of teaching would fall. The difficulty of choosing the best students has brought into prominence the ways by which they are admitted. The common portal of entry, recommended in the Norwood report but not yet established, is a long-overdue reform. A boy trained at a northern grammar school for a specific examination sponsored and accepted for matriculation by a nearby university was recently refused admission elsewhere in the country because that examination is not recognised by other universities as qualifying for matriculation. The schools which insist on individual entrance examinations should acknowledge the burden that these place on candidates, and agree to a common entrance examination. In the year before leaving school young women, uncertain of acceptance at any one centre, sometimes sit no fewer than five separate entrance examinations, besides those for university scholarships and higher school certificates, from which they may hope to obtain State scholarships or county grants. No adolescent should be subjected to this unnecessary strain.

If intelligent primary selection by examination has not advanced in recent years, great strides have been made in other methods of selection. It is now generally recognised that a candidate who satisfies basic requirements in general education is not necessarily fit for a career in medicine, and, in fact, that medicine calls for qualities which cannot be assessed on the results of a competitive examination. It is therefore customary to interview candidates and to assess their personality, interests, and cultural background, with the help of a headmaster's report. At the London School of Medicine for Women, where 400–500 apply each year for 100 vacancies, the first 200 in the entrance examination are interviewed by a committee of five, sitting separately. A committee in full session has been found to overawe candidates, whereas the friendly personal interview is altogether less forbidding. After talking to ten or so applicants, the committee members meet and exchange opinions while these are still fresh in their minds; and the system has worked well Most schools set great store on this preliminary interview, which can help to eliminate those who seek to enter the profession purely for financial gain, and others who, not knowing what they want to do, are pressed by eager parents to adopt medicine as a career. We suggest that the time has come for the more conservative schools, which rely simply on school records, testimonials, and photographs, to employ more modern methods. Selection, however careful, is not infallible; but mistakes are made much more rarely than with no selection at all. If an examination is used for initial screening of candidates it should be designed to test general intelligence rather than factual knowledge.

It remains true that no test other than that of practice can finally prove whether or not the applicant has a bent for medicine. A boy or girl who has shown great aptitude for physics and chemistry may make a brilliant pure scientist but a poor doctor; indeed, many of those that eventually make good doctors find in these subjects an obstinate hurdle, largely because they are not shown how they apply to medicine itself. Occasionally a student after admission does not come up to expectations; and then, both to save his own time and in justice to another who would benefit by training, he is displaced as quickly as possible. At the London School of Medicine for Women, for example, the student who fails once in the first year's examination is asked to leave. Elsewhere, two chances are usually given, but careful watch is kept, sometimes through a progress committee which reviews doubtful cases every six months. The strain imposed by a single now-or-never chance must undoubtedly deprive the profession of some good doctors.

EX-SERVICEMAN OR SCHOOLBOY?

Most schools have welcomed the Ministry of Labour's ruling that up to 90% of places in the coming academic year should be reserved for ex-Servicemen.

The grants made to successful applicants under the Government's further-training scheme are probably generous enough to move a few unsuitable candidates to apply; but at all but one of eleven centres recently visited the general quality of men from the Forces was thought to be high. One dean holds that "the top and average are excellent, but the tail may be rather bigger than usual." The authorities have recognised the doggedness that prompts a man, five, six, or more years after leaving school, to return to academic training, beginning, more often than not, with the matriculation examination. This group has the tremendous advantage of mental maturity and judgment, so often lacking in the young students of the war years; their work may benefit, too, by the wish, not so acute in the younger, to qualify and become independent with the least possible delay. They deserve first consideration, in common fairness, but the claims of those they displace must not be overlooked.

This year the medical schools will be unable to take more than a few chosen schoolboys; the remainder will join one of the Forces, in which they may serve for two years before starting their medical training. Most educators complain that medical students are subjected to continuous and usually concentrated teaching, always under the duress of examinations, from early youth up to the twenties. There should, they reason, be a break between school and medical training, so that the decision to take up medicine, and the course of study itself, may be approached with adult judgment. Such a break, they argue, is needed more by the medical than by any other student, because in medical training he finds a course so concentrated as to offer him little chance of mixing with students in other faculties; and indeed by reason of numbers, community of interest, and lack of opportunity (for apart from Oxford and Cambridge few universities have an established college life) almost his sole companionship is with other medical students. Some teachers therefore welcome the break enforced by military service; they advise those submitted to it to seize this chance of broadening their outlook, and to further their general education with the help of the Service educational authorities. Military training is said by a few to foster mental idleness and disinclination for study, but the keenness of those already released contradicts this rumour.

However, the system has its grave drawbacks, prolonging the period of dependence and postponing the prospect of marriage beyond even the advanced age customary among doctors. Certainly a schoolboy may get a good insight into Service conditions; but if he is ever recalled to the Services, it will be not as a combatant soldier but as a doctor. It would therefore be a gain for the Forces if he did his period of service after qualifying, when he is able to acquire the special techniques of Service doctoring.

CUTTING THE COAT

Most medical schools, and certainly the smaller ones, want to expand moderately as the Goodenough Committee advised. At most centres (Edinburgh is a notable exception) greater numbers could easily be accepted in the clinical years. There are, however, serious local difficulties. One school at least is noticeably short of clinical teachers because these are still being claimed by the Forces; others, usually because they need new buildings, have too few patients in their principal hospital. This second obstacle could undoubtedly be surmounted by closer liaison with municipal hospitals—which some teaching bodies are reluctant to achieve, partly because former relations with these hospitals have not always been of the happiest, and partly because they are not conveniently near. But the war has shown that the arrangement, however tiresome, is workable. Nearly all schools are increasing the number of their teaching appointments; at Birmingham two junior chiefs are now being appointed in place of one, because a call for consultants at the periphery is expected.

The difficulties at most centres are more stringent in the premedical and preclinical years. Unlike the schoolboy entrants, few ex-Servicemen have passed the first M.B. examination; thus there is now a bottle-neck in the first-year departments. When faculties of science are responsible for instruction in the first-year subjects—physics, biology, and chemistry—the medical student may sometimes receive less than his due. Not unnaturally teachers in these faculties are apt to think first of training pure scientists from whose ranks their own future teachers and research-workers will be drawn; and they can hardly be blamed for doing so when the country is as short of pure scientists as of doctors. The Barlow Committee estimated that Britain in 1955 will be 26,000 short of the required total number of scientists, even if universities train men to their full capacity in the intervening years. These faculties also train dental and veterinary students, besides those who instruct school-teachers, and those learning domestic science, nursing, and physiotherapy; and each of these groups is short of personnel. Some think that medical schools might give up teaching these preliminary subjects and accept students only from the beginning of the second year. Each year a small proportion fail in the July examinations, and thus a small but unpredictable number are unable to take the places allotted to them at the start of the second year. If a common school for premedical teaching were shared by two or three medical schools, no second-year vacancies need be wasted. But this would favour mass-teaching, against which modern opinion has set its face; it would deprive the first-year student of medical-school life, from which he is believed to benefit even at the start of his training; and it might delay that revision of first-year work and its closer association with clinical medicine which is the ambition of most teachers.

BUILDINGS AND STAFF

Numbers are further restricted by lack of laboratories and of teachers in the technical subjects. Before the war, many schools had plans for expanding these departments, which even then were too small for teaching or research or both. None of these plans have been carried out; and now the demand for teaching has grown and may be expected to grow still further. Charing Cross Hospital seeks to relieve the burden on King's College by building a new temporary department for the teaching of anatomy and physiology, to start work in October, 1947. Other schools have no such immediate prospect. At a few, the sole obstacle to the acceptance of more students is the lack of laboratory space. These are making the utmost use of existing buildings by lding classes in duplicate and triplicate; but this an inconvenient arrangement, with limited possilities, and, unless teaching staff and research space n be correspondingly multiplied, may even lead to generation of teachers into hacks. It is a disturbg thought that, despite the growing need for octors, suitable students are being turned away mply for lack of a building. A comparatively nall amount of work on repairs and construction ould make a very big difference, and we trust at the Government will favourably consider e proposal that two or more firms of building ontractors should at once be allocated to the niversities in order that it shall be done. With ach aid, if priorities were rightly chosen, notable xpansion would be possible within a couple of years; hereas if the claims of domestic building are rigidly nd exclusively enforced the development of essenial teaching institutions will be indefinitely, and angerously, postponed.

Buildings, however, are only a means to an end, nd usually the problem of space is complementary the far more difficult problem of staff; for existing affs are too small to make full use of new and rger buildings, while larger staffs could not be ontained in those now in use. Moreover, though ew departments could be completed in a year r less, useful additions to the teaching and esearch staff could not be trained in less than our or five years.

The medical schools want, above all, to avoid rogressing in a series of jerks; but that is exactly hat they may be compelled to do by their ignorance f when and to what extent their demands are to be net. The best they can now do is to train staff, while waiting for new buildings to be constructed t some unknown date in the future. Throughout he war those who would normally have taken such raining helped to meet the call for clinicians, and here is today such a shortage of trained biochemists, hysiologists, anatomists, pathologists, pharmacoogists, and bacteriologists as may not be made good or a generation to come. Not only must these men be rained, but the country's impaired prestige in research nust be restored. It is a giant task, but fortunately he right kind of men are volunteering in increasing umbers. The rising trend of university salaries has ttracted some, and the anticipated "flattening" of remuneration in the new health service has moved others to select an interesting career in teaching nd research. Some universities—notably Birmingam, where money has been set aside for training nen in the ancillary sciences and where a research nstitute is contemplated—are doing their utmost o overcome the deficit. In the final count, a man's eadiness to join the staff of a department is decided argely by the reputation of its head and by its esearch programme. Of late years some men with he keenest minds have been inclined to give up eaching and concentrate solely on research; this hould be checked, for students benefit greatly by ssociation with those who are at the growing-point of their subjects. Instruction by those that teach rithout at the same time engaging in research legenerates all too often into coaching. Thus whenver new and larger laboratories are built for students, uitable research accommodation must be constructed for those who will teach. If classes are too large there is always a danger of mechanical and impersonal teaching; and when numbers go up without a corresponding increase in staff, teachers are robbed of so much time for research, which may cause some of the best to withdraw completely from teaching.

NEW SCHOOL FOR WOMEN?

If competition for medical training is now keen among men, it is, and has long been, keener among women. Even the gain, in 1947, of 15% of vacancies in the London men's schools will bring little relief, since the London School of Medicine for Women is to take 15% of men. Those responsible for the training of women students do not, on the whole, favour the enforcement of this 15% quota on schools which are reluctant to accept the agreement. They think that either a few schools should accept men and women on a fifty-fifty basis, thus becoming truly coeducational, or that an entirely new school should be established. They contend, too, that places should be awarded by open competition, regardless of sex. One of the schools which has accepted women students in the last few years only has found them intellectually and personally acceptable and would willingly take more; some of the others demur at the prospect of accepting women, reiterating traditional arguments which in practice have little substance. The common complaint that the training of women is a waste of time since they often marry or otherwise retire is not substantiated by a recent survey which suggested that the proportion of those qualifying who are totally lost to medicine through marriage and all other causes—including retirement at 60—may be under 15%.

The survey was undertaken by the Medical Women's Federation in 1944. A questionary was sent to the women graduates of 21 British medical schools, and 4369 replies were received. Of these women, 3179 (73%) were in full-time and 574 (13%) in part-time work. They included 660 women under 30, of whom 83% were in full-time and 7% in part-time practice. Of 2865 women in the main working years of a doctor's life—between, that is, the ages of 30 and 59—75% were in full-time and 14% in part-time practice; so the proportion lost to medicine between these ages was only 11%. After 60, of course, there was a steep rise, 48% going out of practice.

Women clearly deserve a large share in any further increase in student accommodation. Despite the Goodenough Committee's recommendations, we suggest that the West London Hospital, which has done much for the instruction of women students in the war, should not lightly be abandoned as an undergraduate teaching centre. The successes of its students in examinations, and the growing inclination of entrants to place it at the head of their application list suggest that it should be developed rather than suppressed. Many competent observers believe that this nucleus could well be used as a basis for a new school, especially since there is little immediate prospect of having one elsewhere in the country.

Outside London the foundation of another school must wait upon the granting of a charter to a new university. Even then, ten or possibly twenty years would be needed to build up its staff and organisation. When the time comes, two parts of the country may be considered: the south-west and the East Midlands. The south-west is now served by Bristol, with a domain from Gloucester to Land's End—a stretch as long as the distance from London to Blackpool. Of the possible sites Plymouth is well placed for clinical teaching, but Exeter already has a college which has shown drive and initiative. For the East Midlands, Nottingham has a well-established college and suitable buildings, but Leicester can advance at least equal claims to recognition as a clinical school.

A COMMON PURPOSE

These prospects lie in the future. Can nothing be done to make a better job of the present? Some of the medical schools give a strong impression of fighting in the dark. They do not know the number of students they will be asked to accept in 1947–48, nor the method of allocation; they have not been told when their urgent building programme can begin; and they have no way of judging the effect of the new national service on the demand for graduates. Each school has vigorously set about righting the damage of war, inspired by the thought that the Goodenough recommendations may be acted on some day. But their efforts, though energetic, are local and only casually integrated. Surely a central body—perhaps a standing committee made up of the deans of all schools—could plan for the country at large, and declare the needs of the schools in a strong voice? This body might well keep a register of all candidates for entrance to medical schools, and set a common entrance examination for the schools which insist on this preliminary. There is no reason why it should have any other executive authority: the schools need not fear to lose their autonomy if such a body is formed—they would, as now, be subject only to the requirements of the General Medical Council. Any attempt to set up a common schedule of teaching for the whole country would of course be disastrous, and the suggested body would be well placed to ward off any such attempt. Its other functions would be to decide, by discussion among its members, which schools had prior claims to new buildings; to use every means to put the Goodenough recommendations into effect; and to act as a clearing-house for teachers, so that those schools which needed additional staff most urgently might have a reasonable chance of getting them. If more graduates were needed, the council of deans could decide at which schools the numbers should be increased, and to what extent. In much of its work the council would be supplemented by the medical-education committee of the University Grants Committee, which might, through the council's activities, be prompted to give a more decided lead.

To be lively and stimulating, medical teaching must always be conducted according to local inspiration and taste. But the training of doctors is a national undertaking. The schools should see themselves as a team, serving the whole country not in a narrow spirit of rivalry but as component colleges in a national university.

Air Marshal Sir Harold Whittingham, F.R.C.P., has been appointed medical adviser to the British Red Cross Society.

The Teaching of Anatomy

It has long been customary for teachers to admit that their students have too much to learn; yet the load grows automatically, year by year, with each advance of medical science. The sympathetic teacher in fact usually favours ruthless pruning of everything except his own subject; and this he successfully resists. On the preclinical subjects the Goodenough Committee held that there is "an urgent need in every school for a new viewpoint" and for the drastic elimination from the curriculum of a mass of detailed information "which serves only to clutter up the student's mind and deaden his interest in subjects that can and should make the liveliest appeal to him." And indeed it is very widely agreed that the anatomical burden, especially, is too heavy. The General Medical Council have not yet published their plans for overhauling the students timetable, but while we wait for these we might try to fit the anatomical curriculum for its proper task of training general practitioners.

Let us then begin by reducing the enormous volume of factual memorisation which topographical anatomy inflicts on students not destined to become surgeons. And here a notable step has now been taken by Prof. W. E. LE GROS CLARK, F.R.S., whose *Practical Anatomy Revised and Rewritten* is to appear next month.[1] His preface shows a welcome change in the oppressive anatomical wind which has hitherto prevailed.

> "The fact is," he says, "that current anatomical textbooks have developed and expanded by a process of gradual accretion from the days when the subject was still in its early descriptive stage, when the interest of the anatomist was mainly focused on rather abstract problems of morphology, and when (before the modern organisation of medical services, had been developed) almost any general practitioner might be called on to attempt major operations of an emergency type demanding a fairly intimate knowledge of topographical anatomy."

Probably less than 5% of medical students, he remarks, will ever undertake major surgery.

> "It thus appears unnecessary that the remaining 95% should still be required to study and memorise factual data whose importance lies solely in their application to specialised operative technique. The few who later decide to take up surgery as a career should be required, after qualification, to complete a further course of dissection, including all those details of topography which are or may be of direct importance for the surgeon."

He thinks the student's knowledge of topographical anatomy should be sufficient for the following purposes:

> "*To provide a basis for an intellectual appreciation* of the morphological principles which determine and influence the organisation of the living body (principles which the premedical course of biology should already have instilled to some extent); "to interpret in terms of structural organisation the normal physiology of the human body (and therefore to anticipate the probable results of interference with normal structure and structural relationships); to recognise the anatomical basis of the clinical signs and symptoms of disorder due to injury or disease; to understand the anatomical factors involved in the development of pathological processes and the possible complications which may arise therefrom; and to employ competently the ordinary methods of examination and treatment (including minor surgery) which involve anatomical knowledge."

---

1. To be published by Edward Arnold & Co., London, on Sept. 12th. Pp. 470. 25s.

He wants the decks cleared, partly to provide more room for

> "the study of morphogenetic principles either in embryological development or in the post-natal growth and repair of tissues, a thorough grounding in radiological and surface anatomy, a more systematic study of muscle actions and joint movements, a fuller consideration of the anatomy of the nervous system and the special senses (with special reference to their functional disorders), and an introduction to the principles and methods of experimental anatomy."

Most clinical teachers will find these views full of common sense; but do they go far enough? Is a "fuller consideration of the anatomy of the nervous system" justified? The practitioner who knows how little of the anatomy of the nervous system he remembers from second M.B. days may well feel that he should have been taught the broad principles of nervous-system anatomy, on which he now depends, rather than a mass of indigestible detail about the caudate nucleus and the bundle of Vicq d'Azyr which bewildered him and obscured the pertinent facts. The neurologist, the ophthalmologist, and the otologist should, like the surgeon, defer the acquisition of special knowledge until they are qualified. Again, does the future general practitioner need to study more systematically the movements of joints and muscles when the orthopædic surgeon or neurologist can advise on cases of difficulty? Surely time saved on topographical detail should be devoted to subjects of great vocational use (such as surface and radiological anatomy) or pre-eminent in educational value (such as the principles and methods of experimental anatomy). The change needed is reorientation of the anatomical course with emphasis on function rather than structure. The preclinical student needs to be fitted by his anatomical knowledge to appreciate more readily and intelligently what is to follow in the clinical years.

Some bold spirits have suggested that the education of the future general practitioner and specialist should diverge at a very early stage and that different courses of anatomy should be provided; but no student in the early stages of training can be sure where his abilities lie; moreover, in these days at least, a decision to marry may oblige him, as soon as he is qualified, to exchange the dream of the consulting-room for the reality of the surgery. Some think it a waste of time for every student to dissect the entire body; but actual dissection gives a familiarity and contact with the structures of the body which cannot be gained from specimens and models There is much to be said, however, for allowing students to attend a few preliminary classes at which an expert rapidly dissects and demonstrates the whole body. The beginner will then start work with a mind oriented to think in systems rather than structures.

Professor LE GROS CLARK's book, with some 450 pages, still seems to us to be on the large side; or rather it combines in one book what we should like to see as two. Not long ago we advocated[2] a revival of the small inexpensive dissecting manual, which can be used for practical work and thrown away when soiled. Students can use such a work concurrently with a textbook designed to give them a coherent knowledge of the systems. Complete accounts of the bodily structures, for the use of teachers, students of surgery, and research-workers, should be reserved for reference works. In covering dissection as well as the fundamentals of anatomy, Prof. LE GROS CLARK has been obliged to approach his subject by regions instead of by systems. Though he seems to us to give much more detail than the general practitioner may reasonably be expected to need, he fears that his fellow anatomists may think he has omitted many essentials. Some light might be thrown on this point by setting a test paper on anatomy to a group of general practitioners of 10–15 years' standing: what they know would surely be a useful index of what they need to know. But whether his book is too long or too short, or of exactly the right length, Professor LE GROS CLARK can be sure that most teachers, and all students, will welcome his positive effort to reform the teaching of anatomy.

Annotations

MORAL AND INTELLECTUAL LEADERSHIP

THE British Institute of Philosophy was founded 21 years ago to serve as a link between philosophy and the everyday world. At its coming-of-age meeting last month it listened to a symposium of papers by a philosopher, a scientist, a divine, and a classicist, on the Need for Moral and Intellectual Leadership. Through all that was said ran an urgent sense of apprehension for the future of our civilisation, now threatened with destruction because science has put in our hands tools of immense power and reach, which we yet lack the wisdom to use in our own best interests. The theme is of importance—not merely of theoretical interest but of plain practical importance—for every educated man, and not least for the doctor.

Viscount Samuel, speaking for and to the philosophers, urged that in this crisis their duty does not end with the serene detached contemplation of human life and human thought; they must emerge from their academic seclusion and say something that will affect human action. That a philosophy can be a motive force, Nietsche is evidence enough; Hitler chose his works as a present for Mussolini. That recent years have heard no clear expression of a beneficent philosophy may be due to the discordant voice and laboured utterance of present-day philosophers, and their greater concern with the limits of human knowledge than with the needs of human welfare. But it is possible, and desirable, that "philosophy, in this country and other countries, condescending to be comprehensible, inspired by a Socratic sense of mission, linking hands with religion, science, and scholarship, may yet renew her great days, teaching the teachers of the peoples and leading the leaders."

Prof. A. V. Hill, F.R.S., described human society today—in scientific phrase, and mild enough at that—as being in a highly reactive state. But reactions in human society, unlike those in chemical mixtures, depend on the initial activity of a few of the members, not on a general bulk initiative. These few are the leaders. Good leaders will use their reason and acknowledge moral principles. The majority of mankind "will respond to leadership, but the leadership, if it is to be effective, must appeal for the most part to feeling rather than to reason. The problem, therefore, is to find leaders who, basing their policy on reason and morality, are capable nevertheless of appealing enough to the feelings of their fellow citizens to cause them to follow." Science, so far as it can do so without compromising its prime loyalty to truth, should make some contribution to that leadership.

Canon Leonard Hodgson, professor of divinity in Oxford, trying to define a creed or philosophy of life, quoted Shaw: "what a man believes may be ascertained . . . from the assumptions on which he habitually acts," whether those assumptions are expressed or implied. A satisfactory creed must be rationally coherent, and it must empirically fit the facts of life and experience. The Christian theologist's contribution to the discussion on leadership is his claim that the events described in the Bible story are of central significance to the proper understanding of human life, and to the development of a satisfactory creed. But Canon Hodgson rightly adds that this claim must be continually subjected to the criticism of philosophy and of experience.

[2] *Lancet*, 1944, i, 569.

Prof. E. R. Dodds, regius professor of Greek in Oxford, was concerned with the responsibility of the universities in training leaders. He condemned the nineteenth-century conception of a university as "a holy citadel of pure scholarship" because it was incomplete. He urged that the universities should today make a deliberate contribution to the needs of a planned democratic society. Their problem is to provide society with the men it needs, and at the same time retain their freedom to pursue truth for its own sake. Their difficulty is that society demands mostly technicians and specialists, whereas society needs leaders with general wisdom, vision, and perspective. Their answer must be a continued effort to train students to think and to judge for themselves, on a broad basis of knowledge and experience, and with absolute intellectual honesty.

These stirrings are not merely pious panic induced by the atom bomb. They are the response of honest men whose social conscience has been moved, who are aware of the process of social integration that is the path of British democratic development, and who feel it their duty to take an active part in it. Most doctors owe some thought to these questions too. For medicine is—naturally and inevitably—caught up in the integration process. Doctors are now confronted with duties to society as well as with duties to the individual patient, and must face and deal with both. The peculiar intimacy of their relations with their fellow men gives them an influence on the behaviour and the mental attitudes of the community more powerful than they realise. The success with which the profession solves its major problem of preserving freedom and initiative within a nationally organised medical service will influence a whole series of similar questions of administrative structure in other spheres of activity. The medical schools, on the one hand more than ever built in to the universities, on the other in close contact with the social and individual problems of health and disease, are well placed to design the bridge between university studies and the human affairs of today, between honest thought and unselfish action. Medicine is in a position to show the world, by example rather than precept, that good leaders cannot be made to order, but that a free and stimulating intellectual climate will favour their development and that recognition and responsibility are their due when they appear. In sum, medicine is no longer an isolated affair between doctor and patient: the relations of both to the community are claiming an increasing amount of attention. In a more closely knit society medicine faces new difficulties, new responsibilities, and a more complicated task. The problem of leadership closely concerns it.

MODELLING IN MEDICINE

MOST of us can recall times, particularly during our dissecting days, when a model of an obscure anatomical recess served to enlighten our perplexity. Models may also be used for demonstrating pathological lesions and for illustrating surgical techniques and approaches. Bulbulian[1] discusses the ways of making them of plaster-of-paris, papier-mâché, wax, plastics, metal, or glass.

Direct freehand modelling, which involves the difficult and tedious procedure of copying, is necessary only for large-scale reproductions of intimate structure, such as cells or parasites. This method, which was used by the Greeks and Egyptians in antiquity for the portrayal of deformities, has now been replaced for general purposes by simpler techniques. A direct cast from the actual specimen is the easiest and best method, the medium being applied over the object to produce a negative cast from which the final positive cast is moulded. With hollow structures like the bronchial tree or cerebral ventricles no intermediate stage is needed, for a direct negative cast can be made by filling the lumen with the casting material. Though the casting method is quick and accurate, care is needed to procure a smooth impression and to impart the correct colouring. Direct casting is sometimes impracticable, as with the irregular surfaces and crevices of surgical exposures and post-mortem dissections. Here an indirect method is used, by making a freehand model in clay or other plastic, which is then reproduced by casting. With this process essentials can be judiciously emphasised and non-essentials eliminated; and it is particularly suitable for such intricate structures as the ear, eye, or embryo in magnification. But it is very lengthy, and the colouring is quite inaccurate unless it is incorporated in the medium from the start.

Finally, various composite models have been designed to illustrate particular techniques; thus for training students in endoscopy a plaster cast of head and trunk can be combined with a modelled lesion at the end of a dummy gastroscope. On another page, Professor de Seigneux describes the use of models made from gelatin on a gauze basis to give the student experience of the appearance of tissues and their consistence to palpation. Though useful in imparting basic principles, especially in obstetrics, models can never replace practice on living tissues; passing a catheter on a dummy urethra or setting a fracture in a limb which does not swell after injury is not the best of preparations for undertaking these operations on patients. It is a pity that the modern increase in the student-patient ratio makes such substitutes necessary.

PHYSIOLOGY OF THE NEWBORN INFANT

THERE may now be little need to emphasise the principle that consideration of disease should be preceded by study of the normal. There are still, however, many gaps in our physiological knowledge, one of the largest being the effect of age on body processes. Physiology, as generally taught, is based on observation of fully grown animals and men. Differences between species are largely neglected; students sometimes feel that frogs are not quite the same as men, but the view of their elders and betters seems to be that physiology is essentially the same throughout the vertebrate kingdom. The effect of age on a normal process is seldom demonstrated; and because few physiologists have interested themselves in the significance of age, progress has been retarded. Pædiatricians, for example, have been hampered in investigations and treatment by not knowing where the normal ended and the abnormal began; they have often been forced to work out the normal and its variations for themselves, and physiology owes these men a debt. Their findings, however, are scattered through the literature, and the time has come for a book on the physiology of infancy, bringing together all this knowledge.

Clement Smith[1] has now compiled just such a book, which will be welcomed by everyone interested in the subject. It is not very long—the second edition will probably be longer—but it is packed with facts, mostly considered and presented, with an invaluable biblio- hy at the end of each chapter. One of the work's t pleasing features is the international character of references ; too often nowadays these tend to have omewhat parochial flavour. The author rightly siders that study of the physiology of infancy must in with the fœtus, but he preserves a nice balance. pters are devoted to respiration, the blood, icterus natorum, energy metabolism and heat regulation, digestive tract, nutrition, mineral metabolism, renal siology, endocrines, and immunity, and each ends h a summary of its bearing on clinical medicine. lden behind the back cover there is perhaps the most ful feature of the whole volume—a table of normal ues.

he material of this book is of great importance to dicine. It underlines the fact that our knowledge of subject has only just begun to develop. Here there uld be no national barriers, no call or excuse for ret research ; and if the spirit of international coöpera- n returns, great advances may be made in the next nty years.

CLINICAL PHOTOGRAPHY

CHEMICAL pathology now enables us to define with most mathematical precision minute changes in many dily functions ; and the clinician is increasingly alive the need for exact records of the changes he observes his daily work. This has prompted several hospitals plan photographic departments, and the Westminster ospital medical school has taken the lead by appointing doctor wholly employed on this work. But interest in linical photography is not confined to hospitals : among e societies the Scientific Film Association and the Royal hotographic Society both have medical groups ; and e Royal Society of Medicine early this year devoted n entire meeting to the uses of photography in diseases f the skin.

The practice of relegating the hospital photographic epartment to a basement room, under the care of a oorly paid technician, no longer suffices. On other ages Dr. Peter Hansell and Dr. Brian Stanford suggest equirements for the promotion of this neglected supple- ent to the clinician's vision. There may be delay before heir recommendations are fully met, if only through ck of trained staff. It is hoped that the schedule for he training of hospital photographers now being pre- ared by the Institute of British Photographers will be ollowed by the adoption of a course and examination which will give trained medical photographers a status imilar to that of trained radiographers ; with the emobilisation of the many who have had special experi- nce of photography in the Forces, there should be no ack of suitable candidates. The recruitment of doctors o supervise the departments may be less easy ; probably ew will at first be willing completely to abandon clinical nedicine and to combine their hobby with their profes- ional training in the work of the photographic epartment. But medicine will be greatly benefited by hose who take the plunge.

GROUP PRACTICE IN AMERICA

DURING the last thirty years medical group practice has extended in the United States, especially in the West and Mid-west. There are, broadly, three kinds of groups, organised to meet varying needs : (1) " reference groups," such as the Mayo Clinic, where there is a staff of over 600 doctors, provide diagnosis and treatment, primarily over a short period, for patients with unusual or complicated conditions ; (2) " diagnostic groups " do no more than make a diagnosis and furnish a report to the doctor referring the case ; while (3) " service groups," now numbering about 500, offer family medical care and the commoner specialist facilities. The groups have formed a central organisation, the Medical Group Practice Council,[1] which held its fourth annual meeting at Princeton, N.J., last May, when it was announced that next autumn the New York University College of Medicine will establish the first medical group-practice unit to be undertaken by a medical school. An account was given of a group-practice unit that looked after the 75,000 workers on the atom-bomb project at Oak Ridge. Within a year the Federal government built in the wilderness the atom-bomb factories and the town of Oak Ridge, together with a 325-bed hospital and the necessary clinics. Before the town was built there was not a doctor within twenty miles of the place. A voluntary health-insurance organisation, the Oak Ridge Health Association, was formed on a prepayment basis and financed by contributions from the employed persons with a government subsidy ; and a complete service of medical care was provided by 50 army doctors working from the hospital. On the average, 600 patients were treated daily at the clinics, the maximum number being about 750. The unexpectedly rapid demobilisation of medical officers after the end of the war led to the discontinuance of group practice at Oak Ridge, where, it was stated, there are now 23 private doctors practising for fees.

Prominent among the questions discussed at the Princeton meeting was how to make known the advantages of group practice to the American medical profession, and particularly to the younger doctors. The Medical Group Practice Council proposes to prepare a manual explaining in detail what experience has shown to be the elements essential for success. The council has, however, already published an interesting pamphlet, *Solo or Symphony*, for the guidance of demobilised doctors contemplating entrance into medical group practice. Its 44 pages contain a remarkable fund of practical information, and it concludes by laying stress on the importance of planning the staff of a medical group to suit the varying local conditions : " You must carefully tailor its size and specialist representation," it is said, " to fit the size and requirements of the community you plan to serve."

ELEVEN PLUS

OUR leading article speaks of progress in the technique of selecting candidates for a career in medicine. Unhappily, despite the Education Act of 1944, there has been no similar advance in the choice of boys and girls for higher education, and some of those who might benefit most by medical and other university training never reach the stage of presenting themselves for admission. The child of the less well-to-do, now as before, gets his last chance of a grammar school, and thence a university education, when he is just past the eleven-year-old mark. Examinations, as is acknowledged in modern methods of choosing medical students, are apt to give a distorted reflection of capacity ; and the objections to relying on them are doubly cogent at the early age of 11. A child may be a "late developer" ; he may, through illness, have missed six months' schooling ; he may, as often happens in the early years, have brilliance but little application ; he may have been unwisely taught ; or he may, again, show himself in a poor light when submitted to the routine of the formal examination. If he is a victim of any of these circumstances, he may fail, and by this single failure the doors to a university education are as good as barred to him before he enters his teens. Under the new Act authorities are empowered to transfer children to grammar schools at a later age, but it remains to be seen how far they will do it.

Children whose parents can bear the cost of continued post-primary education are not exposed to this hazard ;

Students Guide

946 1947

Medical Schools

t OXFORD UNIVERSITY there are staff and accomdation to deal comfortably with some 60–70 students rly. Hitherto, most prospective students have come aight from school, but Service men and women already inquiring about places. The faculty is pertted to accept such students outside the quota, but lack of space and staff set an obvious limitation on mbers the competition for places will be greater than er, and the faculty is therefore discouraging the ceptance of foreign students for the present.

The general post-war policy of CAMBRIDGE UNIVERSITY to maintain the preclinical teaching at its previously gh level, and to develop a school of clinical research d postgraduate teaching in both specialties and neral medicine, rather than attempt to found a comete undergraduate school. This is in accordance with e recommendations of the Goodenough report. Plans r postgraduate work have begun to materialise with e reopening of the department of medicine and with e creation of chairs of experimental medicine and diotherapeutics. Other special departments which are ntemplated include pædiatrics, dermatology, social edicine, and chemotherapy. In all of these special epartments there will be opportunities for research udents and for those seeking training for long or short eriods. In general medicine, the experience gained ith ex-Service postgraduate courses has shown the eed, for the future, for regular courses for general ractitioners of scope and length adapted to their various eeds.

An essential part of this organisation has been he creation of a closer liaison between Addenbrooke's Iospital and the university, the first step being the ssumption of responsibility by the university for the athological and biochemical services of the hospital. ther services are expected to come into close association vith the university, including the regional laboratory ervices and a regional scheme for orthopædic and thoracic urgery and for neurosurgery. All of these plans are esigned to make the university the focus of medical esearch and teaching for the East Anglian Region.

London Schools

LONDON UNIVERSITY bears a different relation to its medical faculty from other universities: where they have one school of medicine each, London has the twelve autonomous schools of the teaching hospitals, as well as University, King's, and Queen Mary Colleges, all of which take medical students for some part of the course. In addition, external students of the university may take their clinical training at the West London Hospital, which is not a university school. The course has now been restored to its pre-war length. Candidates who passed the second examination for medical degrees on or after March, 1945, must now take a clinical course lasting not less than 30 months before entry to part I of the M.B., B.S. examination, and not less than 36 months before entry to parts II and III. The additional final examination which has been held in January or February in the last four years has been given up, and will not be held in 1947 or after. Both the first and second M.B. examinations can now be conducted internally. That is to say, students are now examined in their own schools, working at the benches and with the equipment with which they are familiar, like the students of other universities. The examinations are conducted by an internal and an external examiner; and the man who knows the daily work of the students can help to correct the impression made by a normally good student who is having a bad day with the apparatus and showing to poor advantage. The external examiner's opinion has, if anything, more weight, however; so there is no fear that favouritism might bias the issue. The effect is merely to give the student the best possible chance of doing himself justice.

The students of UNIVERSITY COLLEGE have now been back in their own buildings at Gower Street for over a year, but work is still seriously hampered by lack of space; for Government departments, despite continued protests, continue to occupy most of the useful territory of the school. Candidates for entry exceed the number of vacancies; places are particularly scarce in the first year, where the faculty of science must consider the requirements not only of medical students but of those doing pure science, dentistry, and several other subjects. The number of medical students could be increased only by crowding out some of these classes, all of which are essential. Hardly any young people coming direct from school will get places in the first year, since almost all the vacancies must be reserved for ex-Servicemen.

KING'S COLLEGE is one of the largest schools for medical studies in London, supplying students to four hospitals—King's College Hospital, Charing Cross, St. George's, and Westminster. Arrangements are made by which patients attend the college for clinical demonstrations in applied physiology, by clinicians. The scientific departments fortunately escaped serious damage from bombing, and repairs are now completed. The students hostel was reopened in October, 1945.

QUEEN MARY COLLEGE, now returned to London from Cambridge, has established once more its close contact with the London Hospital Medical College, and a joint committee composed of members of the governing bodies of the two colleges has been set up, as well as a teaching subcommittee, to coördinate 1st M.B. teaching. The numbers of medical students passing through the college during the session 1945–46 are 48 for the 1st M.B. and 24 for the premedical examination. A number of ex-Servicemen have joined the medical classes. All internal students now take the special internal 1st M.B. examination in July.

Post-war reablement is beginning to make some progress at UNIVERSITY COLLEGE HOSPITAL medical school. The many gaps in the ranks of its teachers caused by retirements are rapidly being filled, and the departments are beginning to resume their old activities. Expansion is inevitable, and space in which to expand is the constant demand of every chief. Sites and building permits are being eagerly sought and laboratory equipment is being tracked down. Modifications of traditional methods of teaching are being tried cautiously, with the object of achieving a more logical approach to the study of medicine. Teachers are keenly interested in the unpredictable effects of the proposed new health service on the quality of the students presenting themselves for medical training, and feel more firmly convinced than ever that it is essential to take the utmost pains to choose those who are likely to turn their training to the best account.

ST. BARTHOLOMEW'S HOSPITAL Medical College has now returned to London. The preclinical departments started work in their own college buildings, which have undergone temporary repairs, in April, 1946. The clinical school is partly restored to normal with a new clinical theatre, and the library and museum are again in use. In addition to the hospital in London, St. Bartholomew's is responsible for between 500 and 700 beds at Hill End Hospital, St. Albans. Six months in the last year of the clinical course is spent there on work in medicine, surgery, and gynæcology. Many of the gaps in both the preclinical and clinical staff which occurred during the war have been filled. The clinical curriculum has been lengthened from the two and a half years of war-time to a full three years, and the time students spend in the special departments has been materially increased. Although repairs to the damaged buildings are only temporary, accommodation is adequate. The new refectory in the college has exceeded original expectations, and it is hoped that permanent rebuilding of the college will soon be begun, and that the hospital will shortly acquire premises to be used as a students' hostel.

and, without previous competitive examination, they are free to matriculate at the age of 16 or 17. The bias thus strongly favours the more moneyed section of the population. This issue has a twofold implication—social and national: social in that the universities should, in a working democracy, be open to those most likely to benefit by the opportunities they offer; and national in that the country cannot afford to lose by default any that should be its intellectual leaders. A recent survey suggested that "about 5% (of the population) are as intelligent as the upper half (of the university students and graduates tested)."[1] It is admitted that intelligence should not be the sole criterion in the choice of undergraduates; nevertheless, this survey does indicate—what is indeed obvious—that many who have been denied it would have repaid the nation well for the chance of a university education.

What is the solution? Most enlightened educators seek to spread the net wider, by affording, irrespective of status, equal chances of competing for places at the university. The education committee of the L.C.C.[2] has declared itself in favour of the American omnibus or "multilateral" system, whereby all post-primary students attend a single school, and are educated according to their capacity, the competent being given ample opportunity of proceeding to college or university. In this, however, there are difficulties, including cost, the scarcity of teachers, and the risk of lowering the standard of school and university training if the doors are opened wide; and to these Sir Cyril Norwood adds: "Unemployed intellectual proletariats have emerged in various countries in the recent past, and they have not made for social health. It is unwise to breed beyond the means of subsistence."[3] Nevertheless, on the reverse of the coin we find[1]: "It is possible, though by no means certain, that we should be a better and happier nation if every crossing sweeper possessed a degree in Lit. Hum. What is more certain is that we shall be fortunate if by 1960 our schools and universities are turning out enough men and women with the qualities needed at all the different levels of employment." In the *Times*[4] Mr. William Connely writes:

> "The difference between the two countries [Britain and the U.S.A.] lies in the stage at which the weeding-out process sets in. In Britain the weeding-out occurs at the age of 11 plus; in America, seriously at the age of 22. Which is the more democratic? Which gives the wider opportunity to 'late developers'? . . . America has six times as many university students as Britain. But the important thing is that America has 100,000 postgraduate students—twice the number of undergraduates in Britain. These American postgraduates it is who eventually run the country."

It may be thought that the American system has much to commend it; but, if only for lack of teachers, it will not be seen here in the measurable future. Surrey County Council makes perhaps the nearest practicable approach in its plan to adopt a common system of secondary education for children of 11–13; on their records in these two years their aptitude for subsequent education at the grammar, technical, or modern school, as the case may be, will be assessed. There is some hope that eventually the examination at 11 or 12, to which most other bodies are adhering, will be replaced by consideration of school records, parents' wishes, and any other factor that the education authorities wish to include; but this must probably wait until a standard system has been accepted throughout the country. There is also hope that the initial division at 11 will not be too rigidly maintained, and that the boy who after entry to, say, a technical school shows exceptional promise may still be transferred to a grammar school from which he could proceed to the university. All such modifications as these are welcome.

With the best that can be done, selection will be made before, or in the early years of teen-age. In Britain tradition dies hard; and perhaps traditional education dies hardest of all. New methods, [illegible] their proved success in other fields, are but slowly acknowledged and still more tardily accepted. Even at the age of 11 or 12, the few who are outstandingly clever should by all means be admitted without [illegible] to a grammar school; but the claims of others who show promise, competing as they are for a restricted number of places, should be scrutinised by every method of known value. In the first place, examination results could be checked by intelligence tests; no single test is a valid indicator, any more than a single examination; but the sum of several tests is a guide whose worth cannot be overlooked. Otherwise, personality, interests, and aptitude should all be taken into account; a headmaster's report would have its value, not so much for any comment on the child's zeal for learning (which may be suitably reflected in his school record and by examination) as for the comment on his behaviour and his relation to other children. The present exclusive preoccupation with examinations in the formative years is not only wrong-headed but harmful; it stands damned for all to see in the youth who, having battled his way through the primary and grammar schools, finally reaches the university with a scholarship, exhausted, his intellectual life spent—an orange sucked dry. Others are injured in less overt fashion; concentration on examinations fosters the regard of learning as simply a means to success in the competition for places, so that when the university is finally attained, what should be a liberal education is seen as a series of coach-classes. "There is another matter," says Sir D'Arcy Thompson, F.R.S., "which makes, to my mind, a greater change since I was young; and that is the way men come to the university, not for the love and joy of learning, but for the business of passing an exam. They do not hitch their wagon to a star as so many of my old companions did; they only want a degree, and a job. In short, we have plenty of undergraduates, but a sad lack of students."[5]

If the universities are not to degenerate into technical colleges, those that come to them must arrive with fresh minds, thinking of education as something larger than a method of winning the struggle for advancement and the time to impart that vision is when primary education is begun. But such a reorientation is not possible until the teachers themselves have learned that the number of marks in an examination is not what they have held it to be—a satisfactory guide to competence. Nor can the hapless youth whose future may depend on an examination at the age of 11 be assured of a fair chance to show his merit until this lesson has been learned and acted on. We may disagree on methods of teaching and on methods of testing; but none who is interested in the nation's well-being will deny that any step towards a more rational use of our people's intelligence is a step worth the taking.

PSYCHOLOGY OF STUDY

A CORRESPONDENT who signs himself "Ex-Service M.O." writes as follows: "After taking the London degree examinations, one is amazed at the enormous volume of information the student is expected to digest, remember, and reproduce. Many of us who have recently been released from H.M. Forces have our eye on higher examinations, and would be glad to have some information on the technique of study. What is the best method of preparing for an examination with greatest economy of effort, while carrying on a full-time job? Perhaps some of your readers, including the psychologists, would kindly assist us with their advice and experience."

2. Report of the general subcommittee (no. 5), July 11, 1944.
3. *Times*, August 8.
4. August 14.
5. *Times*, August 9.

During the past session the London (Royal Free spital) School of Medicine for Women has been l, and owing to the continued competition for the 100 cancies available each year. an entrance examination s again held in January to select the successful candi-tes for admission in October: 500 applicants entered this examination. Repairs to the extensive damage the school buildings, caused by a rocket bomb in bruary, 1945, have been carried on throughout the ssion. It is hoped that these will be completed by t. 1. and that all the work of the school will be carried in its own buildings from that date. During the past ssion the physiology and organic chemistry depart-ents have continued to enjoy the kind hospitality tended to them by Guy's Hospital medical school. he school buildings are overcrowded, but until repairs e completed it is impossible for any of the much-needed tensions to be carried out. Facilities for the teaching the clinical students have been increased by the opening of more wards at the Royal Free Hospital, nd by the allocation of a portion of the London Fever ospital, Liverpool Road. to the Royal Free. for use as n annexe. The opportunities for teaching at the lizabeth Garrett Anderson Hospital, which the school as enjoyed for many years, have been greatly extended, nd arrangements are being made to incorporate this ospital among the school's teaching hospitals.

St. Thomas's Hospital medical school is again oncentrated in its old home in London, on the south ank of the Thames opposite the Houses of Parliament. tudents, however. still spend one year of their training t St. Thomas's Hospital. Hydestile. near Godalming, oing inpatient clerking and dressing. There is every ope in the near future that sufficient beds will be open n London to enable the whole course of training to take lace there. The library is well stocked with modern extbooks and periodicals. and under its librarian plays n important part in school life. The museum will soon e open again, while the students' club. with its excellent ining-room and lounge, is available: other amenities re rising from the ruins of war. In teaching, strong mphasis is laid on the correlation of preclinical work ith subsequent clinical training, and by the time he has ompleted his second M.B. every student can use the tethoscope. ophthalmoscope, and auriscope. The nedical and surgical units are awaiting the appointments f new professors, while the pathological department is xpanding. and a chair of bacteriology is being estab-ished. Close liaison is maintained with local L.C.C. ospitals, and Pyrford Orthopædic Hospital is used for eaching. Like other hospitals, St. Thomas's is accepting 5% of women among new entrants. but hopes later to ncrease the annual entry to 20%.

The West London Hospital continues to train women students who have completed their preclinical ourse. This year the entrants will number about 30, which is the largest intake possible under present condi-ions. A number of new junior teaching appointments ave been announced, and the nearby Fulham L.C.C. ospital—where the dean of the school has been ppointed to charge of beds—is being increasingly used or clinical instruction. The future status of the hospital as an undergraduate teaching school is still under onsideration.

Westminster Hospital again has all its clinical students under one roof and in the past year has developed many of the plans made during the war for expansion and improvement. Arrangements are already being made to affiliate the hospital with other hospitals in the neighbourhood, and a professorial unit in clinical pathology, staffed and equipped to serve the whole group, has been established. The photographic department has been considerably strengthened, and a flourishing visual education unit has already developed. The Emergency Medical Service still has possession of some beds in the hospital, which makes it difficult to meet the urgent demand for postgraduate instruction: but courses have been arranged for regular officers of the Royal Army Medical Corps. and many old Westminster students released from the Forces have attended the practice of the hospital. It is hoped. moreover, that a number of beds at present used by nursing and domestic staff will shortly be released. for the Empire Nursing Home, in Vincent Square, has been purchased and is being prepared for their occupation. A hostel for students within easy reach of the hospital has been acquired and is already well filled. The clubs of the students' union are extremely active and many athletic and social functions interrupted by war have now been resumed.

The School of Dentistry of the Royal Dental Hospital of London admits students who have passed their science examination in zoology. botany. physics, and chemistry. They take courses in dental mechanics, metallurgy. and special anatomy for the first two years. and during this time they also study general anatomy and physiology. The anatomy and physiology courses are held at King's College in the Strand. For general medicine and surgery the students attend clinics at Charing Cross Hospital. There are also dental schools at Guy's. University College Hospital. King's College Hospital. and the London, but the other London medical schools offer no organised teaching for dental students; medical students of those schools, however. who wished to study dentistry could. of course. be credited with the general courses they had taken there.

Other English Schools

The University of Durham has restored its curriculum to the normal length with effect from the commencement of the academic year 1946–47. At the same time, new regulations for the final M.B., B.S. examination will become operative. and the first examination under the new regulations will be held in December, 1946. Under these regulations surgery and midwifery will form part I of the examination, and medicine and pædiatrics part II. It will be possible for students to present themselves for part I six months before they take part II. The demand for entry to the medical school remains, as elsewhere, very high and is accentuated by the large number of ex-Service applicants. The last year has seen the foundation of a department of surgery, under a whole-time professor, and the appointment of the Nuffield professor of industrial health. Senate has recently agreed in principle to the appointment of a whole-time professor of mental health and a whole-time reader in anæsthetics. These departments are likely to be established shortly.

With the return of many members of the staff from overseas the medical school of Birmingham University * is gradually returning to normal. Important new research schemes are being developed and teams are being built up for this purpose. It is hoped to announce in the near future appointments to the full-time chairs of medicine. surgery, midwifery, and pædiatrics. No outstanding changes have been made in the curriculum. but like other schools Birmingham will shortly be considering the suggestions made in the Goodenough report and the draft recommendations of the General Medical Council regarding professional education and examinations. The public health courses for the C.P.H. and D.P.H. will be resumed in October, 1946.

At Liverpool University,* where teaching of medicine dates back to 1789, there are today 16 professorial chairs and 585 students. The premedical course is taken in the faculty of science, and the preclinical course and clinical lectures in the medical school block, in the university quadrangle. The Royal Infirmary. where some of the clinical work is done, backs on to the university medical buildings. The damage done by bombs is now well on the way to repair. and new quarters are being provided for research laboratories and as offices for the department of surgery. The university has lately appointed whole-time professors in the clinical departments of surgery, and of obstetrics and gynæcology, and is preparing to appoint a professor of neurosurgery in the newly founded department of neurology. The department of child health,

---

* The entrance requirements for the Universities of Manchester, Liverpool. Leeds, Sheffield, and Birmingham are laid down in the pamphlet *Qualifications for Entry upon a Degree Course*, copies of which may be obtained from the Secretary to the Board. 315. Oxford Road, Manchester, 13. War Emergency Regulations are also in operation but will be withdrawn on Dec. 1, 1947. Any candidate satisfying those regulations before that date will be qualified to enter upon a degree course at any time. Additional faculty requirements may, however. be imposed: details can be obtained from the dean of the faculty of medicine in each university.

At CHARING CROSS HOSPITAL plans are complete for restoring war damage and for receiving women students. To relieve the bottle-neck of the preclinical years it has been decided to return to the school's original practice, and to teach anatomy and physiology on the spot, instead of sharing the opportunities offered at King's College. A new story to house these departments is to be built on the top of the present medical school, and will be in action, it is hoped, by October, 1947. These quarters, however, are merely temporary, for Charing Cross, following the Goodenough recommendations, plans to rebuild on an outlying site, near Harrow. A plan has been drawn up with the Middlesex County Council to provide, subject to the provisions of the new Health Bill, a teaching centre and a medical service for the area. The planning committees have striven to eliminate the spirit of competition from this combined voluntary and municipal scheme and to devise a truly coöperative centre of teaching and treatment. The new Charing Cross will be associated with a group of general and special hospitals, including the Central Middlesex and Redhill County Hospitals, the Hillingdon County Hospital, Shenley Hospital for Mental Diseases, Willesden and Hendon Fever Hospitals, Harefield for tuberculosis, and Mount Vernon for radiotherapy. The new centre will therefore serve the greater part of North-west and West Middlesex, with a population of a little over a million. The medical school will be incorporated, and have its own governing body; it is planned to admit a maximum of 100 medical and 50 dental students of both sexes yearly. All teachers will share equally the advantages and obligations of their position and the chances of academic promotion, whether employed by the voluntary or the municipal body. The new Charing Cross will take 100 chronic sick, and will have 300 beds for the admission, without selection, of patients in need of treatment in the area. There will also be 100 maternity beds, 250 beds for general and 80 for special surgery, 20 casualty beds, 210 general medical beds, 100 children's beds, and 114 beds in the special departments. An acute psychiatric unit of 40 beds has also been planned to work in conjunction with the county mental service, and a chest clinic, with 30 beds for tuberculous cases. This is by far the most constructive plan for collaboration between a voluntary hospital and a municipal service so far put forward; it deserves great success.

At ST. GEORGE'S HOSPITAL the tradition is to teach a relatively small number of clinical students in an intimate and individual atmosphere. It is the aim to preserve the spirit of this tradition in the hospital and a medical school of much greater size and scope which is to be built on a new site. In the interim before the move the staffs of both school and hospital are being augmented —a process bringing particular advantage to the present students whose numbers will remain the same until the clinical resources have grown greater. In the coming year the total number of beds at Hyde Park Corner will be increased by thirty for maternity cases. Neurosurgery, medical neurology, and psychiatry will be taught both there and at the Atkinson Morley branch; and pædiatrics at Hyde Park Corner and in the Victoria Hospital for Children, Tite Street, which is conveniently near. Fevers will then be the only clinical subject studied outside the parent hospital and its associates. This year the school will again accept a limited number of women students for clinical studies.

GUY'S HOSPITAL is now back on a pre-war basis, with the exception of those portions which were destroyed by enemy action. All the senior members of the staff have returned from the Forces, and with very few exceptions the junior staff are also back. The medical wards are in use again, and all those surgical wards which were *not structurally damaged have* been reopened. Beds are still retained at Orpington for the special departments (orthopædics, genito-urinary, and E.N.T.). The preclinical school has been working to capacity during the year, and the majority of the entries for the coming year are ex-Servicemen. Applications for admission *this year have* been extremely heavy but are limited by the accommodation available.

KING'S COLLEGE HOSPITAL medical school has now returned to Denmark Hill, except for the special departments of medicine and surgery, which are continuing at Horton Emergency Hospital, Epsom. Tuition in elementary medicine and surgery, pathology, midwifery and gynæcology, and medical clerkships and surgical dresserships, as well as outpatient instruction in the departments, is being carried on at King's College Hospital. At Horton Emergency Hospital, where nearly 1000 beds are available, inpatient teaching on special subjects, including medical and surgical diseases of the chest, is available during *the latter half of the* second clinical year. The teaching of industrial medicine includes a course of lectures by the medical officer of a large factory, and also a visit to a factory. In the last clinical year tutorial classes are taken by tutors in the various branches of medicine.

At the LONDON HOSPITAL the number of entrants slightly exceeds the pre-war figure, and the size of the school now is thought to be optimal. There is a large demand for entry among ex-Servicemen; unlike schoolboy entrants, few of these have passed their first M.B. examination, and the heavy *demand for instruction* in the first-year subjects may delay the start for some. The hospital, like others, has plans for rebuilding: both the medical school and the hospital, which is to be of about 1000 beds, *are* to be reconstructed on a nearby site, but it is not yet possible to say when the work can *be started. During* the coming year the hospital will be maintaining 600 beds at Whitechapel and 300 beds at the *annexe* at Brentwood—in *fact*, more beds than used to be maintained before the war. Both the parent hospital *and* the *annexe* will be used for teaching. All the staff have now returned, and *a* number of new appointments *have* been made recently. A department for medical diseases of the chest has been started, and will work in close conjunction with the department of thoracic surgery. The neurosurgical unit has returned from Chase Farm Emergency Hospital, and is being maintained partly at the London Hospital and partly at the annexe. Arrangements have been made for all students to live at the Eastern Fever Hospital for part of their course in fevers. They continue to visit Claybury Hospital for instruction in mental diseases. A professor has been appointed to the chair of medicine, which has been vacant for some time, and the medical unit has been reconstituted. Professorships of surgery and obstetrics are under consideration. In October there will be six general medical firms, one of which will work in conjunction with the cardiac department, and two others in conjunction with the neurological department. The thoracic surgery and neurosurgery, skins, physical medicine, and psychiatric beds are attached to general medical firms for the purpose of teaching.

At ST. MARY'S HOSPITAL the teaching staff has been considerably increased, partly by the return of members who were in the Services and partly by new appointments. The preclinical and clinical departments have thus been able to overcome most of the difficulties of the war years. Some improvements have been made to the laboratories and to the library; more will be done to the medical school buildings in general as soon as the labour situation eases. All clinical students have now returned from the sector hospitals and receive the whole of their instruction at the parent hospital. The demand for entry in the coming session has been very great, and 90% of the vacancies have been filled from the Services and other priority classes.

MIDDLESEX HOSPITAL students now do their clinical training entirely at the parent hospital, except for a few who still *attend* the Mount Vernon Hospital, Northwood, and the Central Middlesex Hospital. The arrangement for teaching at outlying hospitals has worked well, except that students have been a little hampered by being out *of touch with their own library and* museum. A number of new appointments have been made to the teaching staff, particularly in the junior grades. It is hoped that war damage will have been repaired, and the hospital completely reopened, in 6–9 months. The system of resident instruction in infectious diseases, *recommended* by the Goodenough Committee, has now been adopted, thanks to the coöperation of the L.C.C. The students feel that this way they get better instruction, and certainly the results hitherto have been encouraging.

Scotland

ABERDEEN UNIVERSITY has seen a busy and interesting ar. The members of the staff returned from service tled quickly to their old duties, and demobilised young aduates have shown a refreshing eagerness to get down the task of equipping themselves for their life's work. ere is increased activity in all branches of university ork. An appointment has been made to the chair of ental health, and clinical teaching of this important bject has been begun in the general hospital. A chair child health is to be established. New lectureships have en advertised in nearly all departments and some of em have been filled, but there seems to be a dearth of itable candidates for posts in the medical sciences—e result, no doubt, of the long period when young ctors had to go into the Services instead of being ained for this work. It will take several years to fill is unfortunate though inevitable gap. A full-time ost has been established. the holder of which will be in edical charge of all students whose homes are not in berdeen and of the nurses in the main teaching hospital. e will be expected to devote considerable attention to at aspect of social medicine which is concerned with the fluence of environmental conditions on mental and hysical health. Periodic medical examination is now mpulsory for all students entering the medical faculty, nd optional for the others. Plans have been prepared extend the hall of residence to accommodate 100 udents, and it is hoped that the necessary authority build will not be too long delayed; for, as in other cottish University towns, the lodging problem is becom-ng one of great difficulty, especially during the summer onths. and the importance of communal life as an tegral part of the education of students is becoming ore widely recognised.

At EDINBURGH UNIVERSITY there have been no mportant alterations in the medical curriculum, though etails of courses are constantly under review. The eneral Medical Council have not yet issued their ecommendations on the curriculum and the professional xaminations, on which a general revision of the course ill have to be based. The number of applicants for the LB. degree course beginning next October is expected o reach 1200–1300, and the Government decision hat ex-Service applicants must be given preference. f necessary to the extent of 90% of total admissions, must of course lead to the rejection of larger numbers f young people from the schools than has ever been he case before. Courses for the diploma in public ealth were resumed last January, and all places for the econd course, which begins in October. are already illed. It has not yet been finally decided to divide he course for the diploma in medical radiology into two ections—radiodiagnosis and radiotherapy—but it is oped to introduce separate courses in the two branches ext October. Many applications have been received or this course but it is unlikely that more than 12 andidates will be accepted. Courses for the diploma n tropical medicine and hygiene were resumed last January. Courses for the diploma in psychiatry are still n abeyance: completely new regulations are under onsideration. The university is considering the institution of a diploma in industrial health.

SURGEONS HALL. the school of medicine of the Royal olleges of Edinburgh, is a teaching body only, and holds no professional examinations of its own; it offers courses for the qualifying examinations of the Scottish, English, and Irish Conjoint Boards. The school is not a part of the university.

The faculty of medicine in the UNIVERSITY OF GLASGOW is now working almost normally. All the departments in the university and the associated hospitals are operating, and the teaching staff has almost regained full strength. The faculty admits 180 students annually to first-year medicine, and a small number of exceptional cases to the later years of the course. Selected candidates are interviewed. usually in July, but special arrangements have had to be made this year for ex-Service candidates. Women students are admitted on equal terms with men; and owing to the relatively larger number of women applicants. the educational standard of women admitted is very high. The curriculum at present extends over five years. but it is likely that a six years' curriculum, which was about to be introduced in 1939, will soon be brought into force, having first been reviewed in the light of official recommendations. The war-time arrangement of examinations, under which students have been able to graduate in a minimum period of four years and nine months. is being continued for the present. Four large general hospitals are associated with the university for clinical teaching in medicine and surgery. Obstetrics and gynæcology are taught mainly in the Royal Maternity Hospital, and pædiatrics in the Royal Hospital for Sick Children. The special subjects are taught in the appropriate departments of the numerous hospitals in the area. A large amount of postgraduate teaching is also undertaken. and it is intended to enlarge this field. Medical students join in the full life of the university, associating freely with students in other faculties. There are two large halls of residence for men students and two smaller halls for women students. and lists of private lodgings are kept by the Students' Representative Council. The Students' Unions occupy separate buildings within the university precincts. All students become members of the University Athletic Club on matriculation, and there is a Senior Training Corps, an Air Squadron, and a University Naval Division.

About 20 bursaries in medicine are available each year, and various additional bursaries, prizes, and scholarships are awarded to the best students in the faculty.

The extramural schools at Glasgow, ANDERSON COLLEGE and ST. MUNGO'S COLLEGE. offer courses in preparation for the examinations of the licensing boards and the universities.

Every final-year student of the UNIVERSITY OF ST. ANDREWS graduating in June. 1946, has held a resident hospital post. In future, owing to the claims for further instruction of medical officers returned from H.M. Forces, this may not be possible. The hospitals which applied for these clinical clerks have been favourably impressed with their work. as shown by reports from hospital authorities. The university has now reverted to its peace-time pattern in its examinations, the final examination being taken after 33 months of clinical study. Arrangements are being made to resume the course for the diploma in public health. but unless an appropriate whole-time lecturer can be found there may be some delay.

Ireland

The School of Physic of TRINITY COLLEGE, DUBLIN, in common with other medical schools. has been besieged by applicants for admission. Ex-members of the school returning from the Armed Forces are receiving priority, and it is proposed to allocate the limited number of places remaining to internal students who intend to take the entire premedical and medical curriculum in the school. Only those who have passed a recognised examination in the subjects required for matriculation to the university can be considered, as all candidates for the medical degrees are required to take the course and examinations for the B.A. degree in addition to the medical curriculum. Except in the case of local applicants, places in the school are allocated each April for the following October. Active consideration is now being given to the problems of reviving teaching for the diploma in public health and it is hoped that it may soon be possible to resume instruction for this diploma.

The conditions under which the diplomas in gynæcology and obstetrics and in psychological medicine are being awarded have been slightly modified.

The SCHOOLS OF SURGERY. Dublin. including Carmichael and Ledwich Schools, are attached by charter to the Royal College of Surgeons in Ireland. Students are admitted by competition in the preliminary examination. and the schools accept women as well as men. The preclinical study of physiology now includes special practical classes in which students, working on each other, are taught the use of instruments and methods used in the examination of the peripheral neuromuscular, cardiovascular, respiratory, digestive, and central nervous systems, of the skin, eye, and ear, and of the effects of exercise. An electrocardiograph and a small X-ray screening apparatus are among the equipment used. At the operative surgery class a course in the practical use of splints. plaster, and bandages has been included.

directed by a professor, was established during the war, and operates in both the voluntary and municipal children's hospitals. Clinical instruction in general medicine and surgery is given in the Liverpool United Hospital, which includes the Royal Infirmary, and in the major municipal general hospitals. Specialties are taught in the appropriate special hospitals, whether voluntary or municipal. As in other universities, various entrance scholarships are available details of which may be had from the Academic Department of the university. Halls of residence are provided for the students. The course has been restored to the full six years, of which at least three (and two at least after the first examination) must be spent in the university; the other three years may be spent in any recognised university or medical school. The university grants four higher medical degrees: *doctor of medicine, master of surgery, master of orthopædic surgery,* and *master of radiology.* The M.D. is granted on a thesis and an oral examination. The university also offers courses and examinations for diplomas in public health, and in tropical medicine and hygiene. Postgraduate fellowships and studentships are awarded on application to selected candidates for 1–3 years' research in all the principal departments of the medical school.

At MANCHESTER UNIVERSITY * a full-time chair of medicine has just been established, and a chair in association with the new department of industrial medicine was established last October. The war-time concession by which candidates were allowed to take the final M.B. examination after 30 months' clinical work is to be withdrawn, and the customary 36 months' work will be required after December, 1946. The courses for the diploma in public health have already been resumed, and it is hoped to renew the courses for the D.P.M. in October, and for the diploma in bacteriology some time next year. The university has taken the useful step of providing a certificate for psychiatric social workers, and the first course will be given this autumn.

In the past year no noteworthy changes have been introduced into the medical course at the UNIVERSITY OF LEEDS,* as adoption of the revised curriculum, outlined in the university's report on post-war planning, has been deferred until the General Medical Council's new recommendations on medical education have been considered. Meanwhile, the administration of the medical school has been strengthened by a new post—that of senior administrative officer. The newly created full-time chairs in medicine, psychiatry, and pædiatrics have been filled, and new chairs have also been instituted in chemical pathology, biochemistry, and pharmacology. Full-time chairs in surgery and in obstetrics and gynæcology are under consideration. New regulations, based on the recommendations of the G.M.C., have been approved for the diploma in public health, and a syllabus has been prepared for a course starting in September. Resumption of the course for the diploma in psychological medicine is being considered, but will not be possible next session. The midwife teachers' certificate course will begin again in October. Honours schools for the degree of B.SC. in anatomy, physiology, biochemistry, pharmacology, and bacteriology have been re-opened for approved medical students, and the course for the ordinary B.SC. degree in physiology has been planned afresh to allow candidates in the third year the option of reading either comparative physiology, work physiology, or nutrition and dietetics. Students preparing to take the diploma in dietetics, awarded by the General Infirmary at Leeds, will either take an approved course in domestic science and attend the diploma course for two years, or take a B.SC. in chemistry and physiology with an additional year of practical instruction at a hospital. The Government's delay in announcing their decision to fill up to 90% of the places with ex-Servicemen has immeasurably increased the difficulty of dealing with applicants for admission to the medical course next session. The pressure, already severe, on laboratory accommodation in physics and chemistry will be greatly intensified by the admission of large numbers of ex-Service people, while of applicants from school only those of exceptional promise, whether men or women, are likely to be admitted in the next two sessions.

At SHEFFIELD UNIVERSITY * the normal curriculum has been restored, and all teachers have returned from National Service; but deaths, retirements, and the institution of full-time clinical departments have necessitated many changes in staff. To cope with the increase in administrative work, a full-time Dean of Medicine will have to be appointed. As usual, the number of prospective students far exceeds the accommodation available, and the problem of duplicating classes will be faced if additional staff can be found. Numerous applications are being received from ex-Servicemen. Plans are being prepared and sites have been bought for building a new medical school and a new teaching hospital, but building restrictions prevent further progress at the moment. Recent new developments have been the establishment of departments of plastic and thoracic surgery. Revision of the curriculum in the light of the Goodenough report will be undertaken as soon as the new recommendations of the General Medical Council on medical education are known.

Since last year the clinical curriculum at BRISTOL UNIVERSITY has been restored to its normal length. A few ex-Servicemen were admitted to the medical school last October, and during the session some of the students who voluntarily broke off their studies in order to volunteer for the Forces have returned. Applications from ex-Service men and women for next October are very numerous, and the accommodation will be taxed to the utmost. Additional buildings of a temporary nature have been planned and will be erected as soon as possible in order to prevent "bottle-neck" departments from being the chief factor limiting student admissions. Considerable increases in staff are also being made to meet the programme of reconstruction of the medical school. During this session the university has appointed its first full-time professor of surgery. Refresher courses have been provided for ex-Service medical officers, and new postgraduate courses for specialist qualifications have been designed. The university now proposes to grant again its diploma of public health, which has been in abeyance for some years, and has also instituted new diplomas in medical radiology and in psychological medicine. Courses for these diplomas will probably be introduced next session. An Edgeworth Prize in physiology has been founded from a bequest made by the late Miss E. E. Edgeworth, sister of a previous professor of medicine.

Wales

THE WELSH NATIONAL SCHOOL OF MEDICINE continues to teach students mainly for the degree of M.B., B.CH. (Wales). For admission to this degree, candidates must normally hold a degree in arts or science requiring three years' residence in University College, Cardiff, before entering the school. During the war, however, and up to the present, this requirement has been suspended for students entering the college who have gained exemption from the premedical courses and examinations. The number of students admitted is governed by the available accommodation both in the college and the school, and is normally between 40 and 50. Any loss during the preclinical years is made up by the admission of students from other universities who are studying for qualifications granted by other licensing bodies. For the forthcoming session the University of Wales, like others, is required by Government decision to give absolute priority to ex-Service applicants who are academically qualified for admission, and it is anticipated that few students, male or female, will be admitted direct from schools. The school is administering for the Ministry of Health the scheme for postgraduate training of demobilised medical officers. The placing of class I officers in hospitals creates a little difficulty in finding resident posts for recent graduates, but an effort has been made to retain a sufficient number of vacancies for them. It is anticipated that this difficulty will not last long, and will not affect those now entering upon their studies. In addition to special courses for the ex-Servicemen and other graduates, courses for the certificate of public health (C.P.H.) and the D.P.H. (Wales), under the new rules of the General Medical Council, are being conducted, and those for the T.D.D. (Wales) in tuberculosis are being resumed.

in May and November, and regulations may be ned from the registrar, Apothecaries' Hall, Black s Lane, E.C.4.

MEMBERSHIP AND FELLOWSHIP

e Royal College of Physicians of London confers Membership (M.R.C.P.), which is obtained by ination. Examinations are held four times in each and medical graduates and licentiates of the college twenty-three years of age may sit for it. Details can obtained from the secretary, Royal College of icians, Pall Mall East, London, S.W.1. Fellows of college are elected annually at a general meeting e college.

e Royal College of Surgeons of England grants a wship to those passing the primary and final .S. examinations. Under the regulations which me effective from the end of 1943 undergraduates ot permitted to take the primary examination, which pen to those who hold a qualification registrable e British Medical Register and graduates in medicine surgery of universities and medical colleges recog- d by the council. Subjects of the primary examina- are anatomy (including normal histology), applied iology, and the principles of pathology. To be itted to the final examination candidates must uce evidence of having been engaged in acquiring essional knowledge for not less than 2 years after ng a recognised medical qualification. Dates of nination have been rearranged so that candidates pass the primary examination can proceed at once he final if they are eligible. Copies of the new lations and full particulars may be obtained from director of examinations, the Examination Hall, en Square, London, W.C.1.

edical graduates who have been registered, or ible for registration, for at least three years may ly for examination for Membership of the Royal lege of Obstetricians and Gynæcologists (M.R.C.O.G.). ticulars of the regulations may be obtained from the etary, Royal College of Obstetricians and Gynæco- sts, 58, Queen Anne Street, London, W.1.

he Fellowship (F.R.C.O.G.) is granted to Members are judged by the Council to have advanced the nce and art of obstetrics and gynæcology.

raduates may become Members of the Royal College Physicians of Edinburgh (M.R.C.P.E.) on passing an mination, particulars of which may be obtained from secretary, 9, Queen Street, Edinburgh, 2.

he Fellows are selected from among the Members the council of the college, and receive the designation .C.P.E.

ellowship of the Royal College of Surgeons of Edin- gh (F.R.C.S.E.) is granted to medical graduates who s the required examination; particulars of the ulations may be obtained from the clerk of the lege, Surgeons' Hall, 18, Nicolson Street, Edinburgh.

The Royal Faculty of Physicians and Surgeons of sgow grants, after examination, a Fellowship regis- ble by the G.M.C. as an additional qualification R.F.P.S.G.). Admission is by examination and subse- ent election. The candidate, who must be a licentiate of faculty or a graduate in medicine of a university or dical college approved by the faculty, may be exami- either in medicine or surgery. A candidate having ctised a specialty for at least 7 years may be examined that special subject if the council of the faculty proves. A candidate may also submit original pub- ed work, and if this is of sufficient merit he may be cused part of the examination. Details may be had m the secretary of the Royal Faculty of Physicians d Surgeons, 242, St. Vincent Street, Glasgow, C.2.

Membership of the Royal College of Physicians of land (M.R.C.P.I.) is granted on the result of an amination, the details of which may be obtained from e registrar of the college, 6, Kildare Street, Dublin. Fellows are elected by ballot from among the Members, d receive the designation F.R.C.P.I.

Graduates seeking the Fellowship of the Royal College Surgeons in Ireland (F.R.C.S.I.) must pass in two aminations, a primary in anatomy, physiology, and e principles of pathology, and a final in surgery. rther particulars may be obtained from the registrar, e Royal College of Surgeons in Ireland, Dublin.

The Faculty of Radiologists offers a Fellowship (F.F.R.) to medical graduates of five years' standing who have spent at least one year in general clinical work at an approved hospital, have practised radiology exclusively for three years, and have held a radiological diploma for at least two years. Candidates are required to pass an examination and submit a thesis. Candidates who hold higher medical or surgical qualifications may be exempted from the examinations in general medicine, general surgery, or pathology. Full particulars may be obtained from the warden, the Faculty of Radiologists, 45, Lincoln's Inn Fields, London, W.C.2.

SPECIAL DEGREES AND DIPLOMAS

The regulations for the following diplomas can be obtained by applying to the examining bodies concerned.

Public Health

A diploma in public health (D.P.H.) is granted by the English and Scottish Conjoint Boards, and by all the universities of the United Kingdom, except Oxford, Cambridge, and Sheffield. Durham, in addition to the diploma, offers the degree of bachelor of hygiene to medical graduates of any approved university who attend courses for part I of the examination at Durham; the degree of doctor of hygiene is conferred on those holding the B.HY. who submit an approved thesis and pass in an oral examination.

Courses for the D.P.H. were suspended at all universities except the three colleges of the University of Ireland during the war, but have already been resumed in most places, with curricula revised to meet the new G.M.C. requirements. The Welsh National School of Medicine is considering a revised course for the diploma. At St. Andrews resumption of the course is being delayed by difficulty in finding a lecturer.

Psychological Medicine

The universities of London, Durham, Leeds, Manchester, Edinburgh, Belfast, Dublin (Trinity College), Ireland (National University), and the English Conjoint Board offer diplomas in psychological medicine. (The University of London also grants a diploma in psychology, taken chiefly by social workers.) The courses for the diploma have not all been resumed. The standard is being reconsidered, and the English Conjoint Board has already issued new regulations which meet in a considerable degree the recommendations of the Royal College of Physicians for a five-years' training of psychiatric specialists. At Manchester it is hoped to begin the D.P.M. course again next session, and Bristol is considering introducing a course of the new type. At Durham, Leeds, Edinburgh, and Belfast courses have not been resumed. Trinity College, Dublin, has made changes in the course. London University is holding courses and examinations under the old regulations.

Radiology

The Faculty of Radiologists grants a fellowship (F.F.R.) which has already been mentioned. The universities of London and Edinburgh grant the D.M.R. Edinburgh hopes to give separate courses in radiodiagnosis and radiotherapy next session. The M.RAD. degree of Liverpool University is granted in either radiodiagnosis or radiotherapy. The London University course is being held as usual. The English Conjoint Board offers two diplomas: one in medical radiodiagnosis (D.M.R.D.) and one in medical radiotherapy (D.M.R.T.).

Tropical Medicine

Liverpool University jointly with the Liverpool School of Tropical Medicine grants a diploma in tropical medicine and hygiene (D.T.M. & H.) and holds a course for it. The University of Edinburgh and the English Conjoint Board grant diplomas in tropical medicine and hygiene (D.T.M. & H.). The Edinburgh diploma was resumed this year; and courses for the English Conjoint D.T.M. & H. will be held again at the London School of Hygiene and Tropical Medicine.

Gynæcology and Obstetrics

Medical graduates who are on the British Register, or eligible for registration on it, may apply to the Royal College of Obstetricians and Gynæcologists for examination for the diploma in obstetrics (D.OBST.). The Univer-

At QUEEN'S UNIVERSITY, Belfast, during the war, despite the absence of many of the staff with the Services, it was possible to maintain a full course of study. The number of students entering was limited, in 1939, to 112—the average number for the preceding three years—but has been raised to 130 this year as a concession to ex-Servicemen. Last year the Government grant to the university was extended, which made it possible to increase the staff, and to create additional registrarships in all the clinical subjects, as well as to strengthen the preclinical departments. The length of the course, shortened to five and a half years during the war, now reverts to six years. The diploma in psychological medicine is available for anyone holding the appropriate qualifications who wishes to sit for the examination. Courses for the diploma in public health are being resumed this year but will be confined to ex-Service candidates who are graduates of the university; not more than thirty can be accepted. The chairs of surgery and public health are now being made full-time appointments. As soon as materials become available the preclinical buildings are to be extended and the clinical departments rebuilt.

The NATIONAL UNIVERSITY OF IRELAND has colleges in Dublin, Cork, and Galway.

At UNIVERSITY COLLEGE, Dublin, the courses for the diploma in public health, interrupted during the war, were resumed last October. Courses have also been instituted for the diploma in child health of the university. It has never been the practice to hold courses at this college for the diploma in psychiatry.

At UNIVERSITY COLLEGE, Cork, the [illegible] has been discussed thoroughly, and in October, 1945 a special committee was appointed to consider changes. A general attempt has been made, without shortening courses, to prune away unnecessary detail, unprofitable practical work, and needless burdens on the student's memory. The college has 16 mm. sound equipment for films, and it is hoped that "if used in moderation it will be a useful weapon." The voluntary and municipal hospitals of the city have agreed to make all appointments of newly qualified men in collaboration with the medical faculty of the college. In future the emphasis is to be on clinical rather than laboratory medicine, and in order to ensure that each student has adequate clinical experience numbers have been limited, and only those who complete their first and second examinations within four years will be permitted to proceed with the course.

At UNIVERSITY COLLEGE, Galway, there have been no changes in the medical course or the regulations governing degrees in the past year.

Degrees and Diplomas

EXAMINING BOARDS

English, Scottish, and Irish Conjoint Boards

THE Examining Board in England of the Royal College of Physicians of London and the Royal College of Surgeons of England examines candidates for the qualifying diplomas of M.R.C.S., L.R.C.P. Candidates satisfying the board's regulations in regard to the preliminary examination in general education are eligible for admission to the premedical examination in chemistry, physics, and biology, and are required to complete the professional curriculum subsequently at a recognised medical school. The emergency regulations introduced as a war measure will hold until further notice. Under these, the medical course has been reduced from 57 to 54 months, and candidates are admissible to the last subject of the final examination after 30 months of clinical study instead of 33. The regulation permitting a candidate to enter for one part of the final after 24 months of clinical study still holds. Some other war-time concessions are still authorised in the regulations: for example, clinical study may be undertaken at any hospital provided the dean of the candidate's school is satisfied as to the instruction available and signs the certificate of study. Other modifications will be found in the Emergency Regulations, copies of which, with a calendar showing the dates of examinations, may be obtained, free of charge, from the secretary to the Examining Board in England, the Examination Hall, Queen Square, London, W.C.1.

The Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow have an arrangement by which, after one series of examinations, held in Edinburgh or Glasgow, or both, the student may obtain the diplomas—designated by the letters L.R.C.P.E., L.R.C.S.E., L.R.F.P.S.G.—of all three bodies. Candidates may work for the examination of the Scottish Conjoint Board at any of the recognised medical schools of Great Britain and Ireland. In 1938 the Triple Qualification committee of management adopted the suggestions of the General Medical Council for an extended medical curriculum, under which the course was to consist of a year of premedical work followed by a five-year medical course; but the committee reverted to the 1937 regulations as a temporary war measure. Under these the course lasts only five years and includes, in addition to the pre-registration examination, four professional examinations: the premedical examination (biology, chemistry, and physics); the second examination in anatomy and embryology, physiology, biochemistry, and biophysics; the third in pathology and bacteriology and pharmacology; and the final in medicine, surgery, midwifery, forensic medicine, and public health. Details may be had from the registrar, 18, Nicolson Street, Edinburgh.

The Conjoint Board of the Royal College of Physicians of Ireland and Royal College of Surgeons in Ireland accept candidates for the L.R.C.P.I. and L.M., L.R.C.S.I. and L.M. from most of the recognised medical schools at home and abroad. Full details of the regulations can be obtained from the registrar, Royal College of Surgeons in Ireland, Dublin.

Apothecaries' Licences

The Society of Apothecaries of London grants the L.M.S.S.A. Lond. to candidates who pass in the primary examination (which is held quarterly) and the final examination. Final examinations are held monthly except in September. The minimum period of study is normally five years. The four parts of the final examination may be taken together or in any order. Regulations and schedule of the required courses of study may be obtained from the registrar, Apothecaries' Hall, Black Friars Lane, E.C.4.

The Apothecaries' Hall of Ireland grants the diploma L.A.H. Dubl. to students who have passed the three professional examinations. The diploma confers on holders the right of registration on the Medical Register of Ireland and Great Britain. Examinations are held three times yearly, in March, June, and November. Further information may be had from the registrar, 95, Merrion Square, Dublin.

UNIVERSITY DEGREES

Bachelor of Medicine and Surgery

All the universities in the United Kingdom confer baccalaureate degrees in medicine and surgery, conferred on the results of examination.

HIGHER QUALIFICATIONS

Those who have graduated in medicine and surgery are at liberty to seek higher qualifications if they wish.

Doctor of Medicine and Master of Surgery

Graduates holding a bachelor's degrees can take the degree of Doctor of Medicine or Master of Surgery. All the universities in Great Britain and Ireland confer such degrees. The requirements vary and can be obtained from the different universities. At the University of Durham the degree of Doctor of Surgery (D.CH.) is offered in addition to degree of Master of Surgery (M.S.). Liverpool offers the orthopædic degree of M.CH. ORTH.

Master in the Science of Obstetrics and Master of Midwifery

The Irish universities grant the degree M.A.O. The Society of Apothecaries of London grants the Mastery of Midwifery (M.M.S.A.) upon examination in obstetrics, pædiatrics, and public health. The examinations are l opportunities for studying preventive medicine hygiene, and aviation medicine.

he DENTAL BRANCH of the R.A.F. is separate from the ical Branch, and appointments are still made ugh the Central Dental War Committee, organised he British Dental Association. Regular commissions still suspended, and candidates are appointed to the .F. Volunteer Reserve.

Health Services at Home

PUBLIC HEALTH

HERE has been steady expansion in the field of public lth since the first medical officer of health was pointed nearly a hundred years ago. In the early s the duties of the M.O.H. were largely concerned h sanitation, especially such matters as the safety water-supplies and sewage disposal. The work of pioneers in this field led to the general acceptance l application of standards; as a result, the need for ailed medical supervision of environmental hygiene been reduced, though in some rural areas there is l much to be done. The medical officer must now ain general control and supervision of the work, he largely delegates it to sanitary inspectors, health itors, and others. So long as the general control nains with the medical officer trained in public health re can be only good in this.

Control of infectious diseases has always been one of main concerns of the M.O.H. The old emphasis on lation of infected persons has now been replaced the provision of modern hospital treatment, but there nains the active home follow-up. Bacteriologists ve made great advances in the identification of different ains within certain of the pathogenic species, and ese new techniques applied to epidemic control have ven the M.O.H. an instrument of precision in much of epidemiological work. The application of specific ophylactic measures against various of the acute fections is now a major function of health departments. uch remains to be done, but the control of such diseases diphtheria and enteric fever is in sight.

During the last thirty years preventive clinical work s come to occupy most of the medical officers employed hole-time in public health work. The organisation of e maternity, infant welfare, and school health services presents a large part of the administrative responsibility of the M.O.H. of a county or county borough. is probable that there will be a steady increase in the rt played by appropriately experienced general practioners in the clinical side of this work, but its administraon must clearly remain with the M.O.H., who is sponsible for other preventive medical work. In unties one may look to the establishment of a divisional rm of administration, in which divisional medical ficers may deal with the detailed administration of ese preventive clinical services and the environmental ygiene in the same area. *This should lead to closer* sociation between public-health medical officers and eneral practitioners. The maternity services will aturally be closely associated with the hospital obstetric rvice, and the school health and infant welfare services ith pædiatric work in hospitals.

The tuberculosis and venereal disease services are ecialist clinical services which must be closely linked ith epidemiological and preventive work, in which oth clinician and M.O.H. are concerned. The provision f treatment is a hospital function, whether outpatient r inpatient, but more is required than this. The ollow-up of contacts in both diseases is of the highest nportance, and in tuberculosis there is a special field f family care. There is here common ground for the .O.H. and clinician which should lead to closer association, even though the hospital service now passes to nother authority.

Hospital administration has been one of the main reoccupations of the M.O.H. of the large county borough or ounty in the last sixteen years. The National Health ervice Bill provides for the transfer of hospital and pecialist services to new Regional Boards. There will be nedical administrative posts in the hospital service of the uture but the public health service, as such, will be freed rom the burden of hospital administration and enabled to concentrate on preventive medicine. The points of contact with the specialist services will be many, and full development of the social services of hospital and health department should lead to closer integration in the future.

The mode of entry to the service will probably not be, as in the past, through the clinical side, but through assistant administrative posts concerned with control of infectious diseases and organisation of clinic services. Thus there will be far less likelihood of medical officers who have taken postgraduate qualifications in public health devoting the rest of their professional lives to clinical work in a limited field. The very fact that those who undertake clinical preventive work will also be engaged in curative work will bring the administrative medical officer responsible for the organisation of clinic services into far closer contact with his professional colleagues.

The curriculum for the diploma in public health has been revised and now provides a first part which is suitable for men engaged in preventive clinical work or for those intending to specialise in tuberculosis or venereal diseases. A certificate is given to those who pass the examination for part I only. The course for part II provides for those who intend to take the diploma and enter the public service. Possession of a D.P.H. is necessary for anyone now appointed as M.O.H.

INDUSTRIAL MEDICAL SERVICES

THE stimulus which war gave to industry brought industrial medicine actively into the service of the country, for output depends on the health and well-being of the workers. The medical services will probably continue to grow in peace-time and it is likely that they will be integrated with the National Health Service. It is not possible to forecast the final form these services will take, but there is no doubt that many doctors in the future will find their life's work in industrial or occupational medicine. University chairs devoted to the subject have been set up at Manchester and Durham, and readerships are being established at Glasgow and Edinburgh. Again, the newly established chairs of social medicine at Oxford and Birmingham take industrial medicine (or industrial health, as it is now being called) under their wings, so students are likely to hear more about this subject in their undergraduate courses. Postgraduate courses are held from time to time in London, Birmingham, Sheffield, and Manchester. Diplomas in industrial health have recently been instituted by the Society of Apothecaries, the Conjoint Board of the Royal Colleges of Physicians and Surgeons, and Edinburgh University.

The term industry includes not only work carried on in factories, but also in mines and quarries, transport undertakings of all kinds, agriculture, and fisheries. Several Government departments deal with various aspects of the industrial medical services. For instance, the Post Office, which employs more workers than any other department, has had a medical service since 1855, and, because it deals with engineering and manual workers in addition to office staffs, is partly an industrial medical service. Other Government departments, such as the Ministry of Fuel and Power, the Ministry of Supply, and, in a minor degree, the Ministry of Health through the local authorities, play some part in controlling industrial health services. But of all the departments supervising industrial health the main one is the factory department of the Home Office, seconded in 1940 to the Ministry of Labour and National Service.

FACTORIES

The factory department administers the Factories Act of 1937, with its regulations on accident and sickness prevention, hours of work, amenities, first-aid and ambulance rooms, and canteens. The staff now numbers 401, of whom 12 are medical inspectors. All members of the department, whether lay or medical, take part in the activities directed towards preventing illnesses and maintaining the health of the factory population. The medical inspectors are at present stationed in London, Birmingham, Sheffield, Liverpool, Manchester, Glasgow, and Wolverhampton, and from these centres are able to deal with factory health conditions in any part of the country. Under them 1750 general practitioners give part-time service as factory examining surgeons, examining all young entrants into industry, and periodically sity of Dublin also offers a diploma (D.G.O.) for which a course is held at Trinity College and the Rotunda Hospital; there have been some changes in the regulations this year. The Mastery of Midwifery granted by the Society of Apothecaries of London has already been mentioned.

Ophthalmology

Three examining bodies issue diplomas in ophthalmology—the University of Oxford (granting the D.O.), and the English and Irish Conjoint Boards (granting the D.O.M.S.). The Royal College of Surgeons is applying for a Supplemental Charter to enable ophthalmological candidates to obtain the F.R.C.S. on passing the ordinary primary examination and a special final examination equal in standard and similar in form to the ordinary examination.

Laryngology and Otology

The English Conjoint Board offers a diploma (D.L.O.) for those who have made a special study of the ear, nose, pharynx, and larynx.

Anæsthetics

The English and Irish Conjoint Boards offer diplomas in anæsthetics (D.A.). Candidates must have special experience in giving anæsthetics.

Child Health

Diplomas in child health (D.C.H.) are granted by the English and Irish Conjoint Boards; also by the National University of Ireland, with a course at University College, Dublin.

Tuberculous Diseases

Courses and examinations for the diploma in tuberculous diseases (T.D.D.) of the University of Wales have been resumed.

Bacteriology

Diplomas in bacteriology are ordinarily granted by the universities of London and Manchester and both are resuming courses next session. The course for the London University examination will be held at the London School of Hygiene and Tropical Medicine.

Clinical Pathology

The University of London offers a diploma in clinical pathology (D.C.P.), for which a year's course of study is required.

Physical Medicine

The English Conjoint Board offers a diploma in physical medicine (D.PHYS.MED.). Candidates must have held a registrable qualification for two years, and must have had two resident appointments occupying not less than a year.

Orthopædics

Liverpool University offers the degree of M.CH.ORTH., and courses for it are being resumed next session.

Industrial Medicine

The Society of Apothecaries of London and the English Conjoint Board have both, during the past year, instituted diplomas in industrial medicine (D.I.H.).

DENTAL DEGREES AND DIPLOMAS

There are schools of dentistry at the universities of London, Durham, Birmingham, Liverpool, Manchester, Leeds, Sheffield, Bristol, St. Andrews, Belfast, and Dublin; and at the University Colleges of Dublin and Cork, in the University of Ireland. Leeds grants a diploma (L.D.S.), a baccalaureate degree (B.CH.D.), and a mastership (M.CH.D.). The University Colleges of Dublin and Cork grant a B.D.S. and a M.D.S., and Trinity College, Dublin, offers a B.DENT.SC. and a M.DENT.SC. All the other universities mentioned except London offer L.D.S., B.D.S., and M.D.S. degrees; St. Andrews offers a diploma in public dentistry (D.P.D.) in addition. London University prepares students for the L.D.S. of the Royal College of Surgeons. Licences in dentistry are also granted by the Royal College of Surgeons of Edinburgh, the Royal Faculty of Physicians and Surgeons of Glasgow, and the Royal College of Surgeons in Ireland. The Royal College of Surgeons of England is applying for powers to grant a higher dental diploma, to be called a fellowship in dental surgery of the college.

The Defence Services

Royal Naval Medical Service

The usual regulations governing entry of medical dental officers to the Royal Naval Medical Service suspended during the war, and the only medical of at present being admitted are those granted temp commissions in the Royal Naval Volunteer Res Candidates for entry must have had at least 6 mo experience in a house appointment. Some vac will be filled by selection of officers from among th who have served in the R.N.V.R. during the war. small number of women medical officers are s as surgeon lieutenants R.N.V.R. and one as sur lieutenant-commander R.N.V.R. (at Medical Departm Admiralty).

Candidates for the Royal Naval Dental Service m be registered under the Medical or Dental Acts and m also have a registrable qualification in dental surgery. T method of entry is similar to that for medical officers

Opportunities are given to medical and dental o R.N.V.R. to apply for transfer to the Perman Service R.N. after about 6 months' service.

Royal Army Medical Corps

No direct applications for regular commissions in th R.A.M.C. are being invited at present. On the nominati of the Central Medical War Committee doctors a appointed to emergency commissions with the rank o lieutenant. Medical officers, after serving as emergen commissioned officers for one year on full pay, now ha an opportunity of applying for a regular short-serv commission under conditions set out in Army Coun Instructions, and may subsequently be considered f permanent Regular Army commissions. The conditi governing the granting of these commissions are a present being revised. Recently qualified doctors wish to be appointed to emergency commissions sh apply to the secretary of the Central Medical W Committee, at B.M.A. House; or if resident in Scotl to the Scottish Central Medical War Committee, Drumsheugh Gardens, Edinburgh, 3. Applicants sh have held an appointment either as house-surgeon house-physician for six months.

ARMY DENTAL CORPS

As in the R.A.M.C., no direct applications for re commissions in the Army Dental Corps have been inv since the outbreak of war. All war-time app ments were to emergency commissions for the dura of the war; but dental officers, after serving as emerg commissioned officers for one year on full pay, h an opportunity of applying for a regular short-ser commission. At present conditions in this service a being reviewed. Recently qualified dental surg wishing to enter the Corps should notify the secret of the Central Dental War Committee, at 13, Hill Str London, W.1, or in Scotland the secretary of t Scottish Central Dental War Committee, c/o the Depar ment of Health for Scotland, Edinburgh, 1.

Royal Air Force Medical Branch

Since the end of the war arrangements in the R.A.F have changed slightly. Commissions in the Medic Branch are still only given to those appointed to R.A.F. Volunteer Reserve, and short service commiss are still in abeyance, but a limited number of perma and extended service commissions are being granted.

Newly qualified doctors must have held a six mont house appointment in a civil hospital before be considered for service in the Medical Branch. Candid must register with the Central Medical War Committ through whom an interview and medical examinati are arranged at the Medical Directorate of the A Ministry. Doctors normally enter the Service with t rank of flying officer and are automatically promot to the rank of flight-lieutenant at the end of a y if recommendations are satisfactory. Specialists en the Service with a higher rank, but vacancies are r tively few. Flying officers begin with a short cou at the Medical Training Depot, and are then posted t operational units, training units, recruiting centres general or station hospitals, at home or overseas. Besi ordinary general medical work, the medical officer h

examination; 18 of them for the final F.R.C.S.
nation and the diploma in anæsthetics, and a
er for the diploma and membership of the Royal
e of Obstetricians and Gynæcologists. Seven general
als and Queen Mary's Hospital for Children, Car-
n, are partially recognised for the diploma in child
by the Royal Colleges of Physicians and Surgeons.

MENTAL HOSPITALS SERVICE

E public mental hospitals in England and Wales
he responsibility of the local authorities. Apart
those hospitals administered by the London County
cil, there are 65 hospitals under the control of
y councils, and 26 hospitals under the control of
y borough councils. The hospitals vary in size
the small borough mental hospitals with about
eds to the large county mental hospitals with over
beds.

cording to the interim revision of the Askwith
orandum published this year, assistant medical
rs to mental hospitals receive a minimum com-
cing salary of £455, rising by annual increments of
o £555 yearly, with emoluments which must include
d, lodging, laundry, and attendance. In addition,
medical officers who possess a diploma in psycho-
al medicine receive a further £50 per annum.
ble provision is made for the accommodation of
ied assistant medical officers. In the higher posts of
ity medical superintendent and medical superinten-
no uniform scale of salaries is laid down, and these
between the different hospitals. In addition to
y, emoluments are provided which usually consist
house, furnished or unfurnished, fuel, and light.
nanent medical appointments are in all cases estab-
d posts within the meaning of the Asylums Officers'
erannuation Act, 1909.

osts at these hospitals offer medical officers scope
initiative and promotion. Very few new appoint-
its were made during the war, and medical staffs
e been much curtailed. There should be good openings
hese immediate post-war years.

he mental health services of the L.C.C. are responsible
a large medical service, vacancies in which are
ertised from time to time. An applicant enters
service as assistant medical officer at a salary
£575 a year, rising by annual increments of £25 to
5. Salaries are graded through the various ranks to
00, plus a cost-of-living bonus of £90 (£72 to £82 for
nen), paid to superintendents of large hospitals: a super-
ndent is also provided with an unfurnished house on
hospital premises. Assistant medical officers may be
uired to live in the institution which they are serving
l to pay fixed rates for board, lodging, and laundry.
icers contribute to a superannuation fund. They are
uired to take a diploma in psychological medicine
hin three years of entering the service and the diploma
ries with it a payment, in addition to salary, of £50
ear. Promotion is reasonably rapid for men.

MINES MEDICAL SERVICE

HE Mines Medical Service now consists of eight
ional mines medical officers, with a chief mines
dical officer and a deputy at headquarters.

he white-paper on coal proposed the establishment
this service "with a view particularly to checking
stage of labour." Thus much of the work of the
dical staff is concerned with applications for release
m the industry on medical grounds. Before the
dical service was founded all such applicants were
t by the Ministry of Labour for independent medical
mination. The functions of the service have been
fold: to relieve the workman of such examination,
he medical evidence put forward by him was suffi-
ntly conclusive: and in doubtful cases where inde-
dent medical examination is necessary, to secure a
h standard of examination. These services have
n of value both to the workmen individually and in
ping to check unwarranted wastage of labour. But
as always been realised that these activities, essential
they are at present, are not constructive, except in
t they lead to better medical or surgical treatment
the patients concerned. From the start the medical
cers have been enjoined to devote all the time possible to professional activities at the mines and in connexion with the hospitals, rehabilitation centres, and other institutions to which the miners go for treatment. Professional work at the mines themselves is increasing in volume. Medical officers have charge of the first-aid and ambulance arrangements both below and above ground; they study the working conditions in relation to the miners' health, and are getting a wide first-hand experience of the coal-mining community at work. Special attention is being given, and will be given increasingly, to a practical study of the causes of the so-called industrial diseases, and to measures for preventing or alleviating them. The field to be covered is wide, and previous work and experience have already shown that there are no easy roads to speedy improvement; but it is hoped to improve conditions gradually by concentrating on particular difficulties and problems. Several studies of this kind are already in hand. The use of morphine for the first-aid treatment of cases of painful injury underground has proved beneficial. A large number of cases have been treated with good results, the drug easing the patient and lessening the shock. The conditions governing the use of the drug at mines are strictly enforced. Various industrial hazards, such as dermatitis, epidermophytosis, Weil's disease, and occupational diseases such as the "beats" and pneumoconiosis, are continuously studied. The medical officers have also prepared the way for the establishment of medical treatment centres at collieries, and for the appointment of State-registered nurses to work in them. The regional mines medical officers will assist in the selection of nurses and will guide and generally advise them at the treatment centres in the early days of their appointment. The medical service is looking forward to the time when the whole of its energies can be concentrated on constructive work of this kind, and in the meantime will devote to it all the time that can be spared from dealing with the temporary problems and difficulties still arising out of the war.

PRISONS

At the larger prisons whole-time officers are appointed, sometimes with deputy medical officers to assist them. Unfurnished quarters are provided or an allowance made in aid of rent. Posts are pensionable and promotions are made as vacancies occur. Candidates with a diploma in psychological medicine receive £50 per annum more on appointment than candidates without this qualification, and are given preference provided they also have good all-round general experience. At the smaller prisons no whole-time officers are employed; local practitioners are usually appointed as part-time officers. Further particulars can be obtained from the Prison Commissioners, Horseferry House, Thorney Street, Westminster, London, S.W.1.

State Boarding-schools.—In the past local education authorities have been concerned with boarding-schools mainly to provide for handicapped children and those healthy children who are unable to attend day-schools. Under the Education Act of 1944 local authorities must see that boarding education is open to all children for whom these authorities and the parents consider it desirable. This has been carried a step further in a Ministry of Education circular (no. 120, H.M. Stationery Office, 1*d*.). It explains the existing resources in county and voluntary, and in direct-grant schools, and mentions the arrangement already reached whereby local authorities may support pupils at independent schools outside the State system of education. It is hoped that these arrangements will be increasingly employed and that the independent schools will be willing to reserve more places for children educated at the public expense. The Minister is now to assemble a small committee to collect precise information of the boarding places in all types of schools available for the use of education authorities (apart from those earmarked for local purposes). At the same time the committee will work out a procedure by which the pooled vacancies can be sought by individual local authorities and can be fairly allocated. Local education authorities will be responsible for the selection of pupils and, where necessary, for payment of appropriate expenses under an approved income scale. The aim is to develop speedily boarding education for all suitable pupils.

all those engaged in dangerous processes. They also issue certificates under the Workmen's Compensation Act for scheduled industrial diseases.

The mines medical service, described below, is responsible for the health of miners. The silicosis and asbestosis medical board consists of 11 whole-time medical officers and some part-time doctors. In addition about 10 whole-time temporary medical officers are employed in the South Wales area to assist in dealing with outstanding claims from miners for compensation for pneumoconiosis. The members of the board have special experience of chest diseases and issue compensation certificates to workers who develop silicosis or asbestosis; they also examine periodically workers in industries liable to produce these conditions. A separate board consisting of three doctors was set up in Manchester in 1941 to supervise cotton-workers who develop byssinosis, and to issue compensation certificates. All workmen's compensation schemes used to come under the Home Office but are now under the Ministry of National Insurance.

FACTORY MEDICAL OFFICERS

Before the war the practice of appointing whole-time or part-time works' medical officers was not universal; then there were only about 50 doctors employed in industry. But, partly as a result of the Factories (Medical and Welfare Services) Order, 1940, made by the Ministry of Labour and National Service, there has been an increase in the number of works' doctors. In 1943 there were 926 of them, of whom 63 were women. Whole-time doctors numbered 176 and part-time 750. The numbers would have been much higher had there not been a great shortage of doctors owing to the call-up for the Forces. During the war the Ministry of Supply built up a factory medical service under a chief medical officer. Both whole-time and part-time doctors were appointed to various factories throughout the country. Many of these war-time appointments are likely to become permanent now the war is over, since employers who experience the benefit of a well-run medical service in a factory rarely abolish it. At present works' doctors, except those in Government factories, are paid by private employers or firms. The workers in some cases tend to distrust the doctors' opinions on this account. Under a comprehensive medical service it should be possible to arrange that the doctor is employed by the State or some other neutral body.

Medical officers of factories who are interested in social problems have wide opportunities for their study and can also undertake the teaching of health and hygiene. They can strengthen the bonds between the factory service and the general medical and hospital services, treat accidents, reduce the chances of sepsis, follow up serious cases, and ensure that patients all return to work in the shortest time compatible with adequate treatment and reablement. Inevitably they will have to play an important rôle in the schemes for resettling disabled persons (whether from the fighting or civilian services) in industry. With their first-hand knowledge of the processes carried out in the factories, and of the physical and mental capacities of the workers, they will be able to place the disabled persons in suitable jobs and keep them under observation.

INDUSTRIAL HEALTH RESEARCH

Apart from the investigations and research into industrial diseases conducted by the medical inspectors of factories, the mines' medical officers, works' medical officers, and examining surgeons, much fundamental research into environmental conditions has been carried out by the investigators of the Industrial Health Research Board of the Medical Research Council. Problems investigated include those of hours of work, lighting and vision, heating and ventilation, accident-proneness, and sickness-absenteeism. The investigations have been mainly physiological and statistical, but clinical studies have also been made under the ægis of the Industrial Pulmonary Diseases Committee of the Medical Research Council, and include inquiries into the pneumoconiosis of South Wales coal-miners and the byssinosis of cotton-operatives. It became apparent that more clinical research into occupational diseases was needed and the council in 1942 appointed a director of research in industrial medicine. Finally, in 1943, a department for research was established under the council at the London Hospital.

The Association of Industrial Medical Officers formed some years before the war by doctors interested in various aspects of industrial health, and branches have been established in various parts of the country. The new *British Journal of Industrial Medicine* is sponsored by the A.I.M.O. in conjunction with the British Medical Association. Information about the association may be obtained from the Secretary, c/o Standard Telephones and Cables Ltd., New Southgate, N 11.

LONDON COUNTY COUNCIL HOSPITALS

THE hospitals service of the London County Council provides special facilities for undergraduate instruction and opportunities for experience for medical graduates who intend either to be general practitioners or consultants or to enter the L.C.C. Public Health and Hospital Service. At the beginning of the war the service contained 97 hospitals with beds for 71,094 patients. The 97 hospitals consist of 44 general hospitals, 32 special hospitals, and 21 mental hospitals and institutions the mentally defective.

Treatment is provided in these hospitals for all kinds of acute and chronic illnesses, including fevers, tuberculosis, mental and nervous disorders.

HOSPITALS BRANCH

Medical superintendents of the hospitals, who are expected to be experienced hospital administrators, receive £1000 to £1800 a year, in hospitals with accommodation for from 100 to 1300 patients. In addition, medical superintendents are provided with an unfurnished house or quarters with payment by the Council of local and water rates.

The other full-time medical staff are classified as:

Grade	Annual sa (ba
Deputy medical superintendent, class I	£850–£50–
Deputy medical superintendent, class II	£800–£30–
Deputy medical superintendent, class III	£725–£25–
Deputy medical superintendent, class IV	£650–£25–
Senior resident surgeon, physician, or obstetrician, and senior assistant medical officer	£650–£25–
Assistant medical officer, class I	£155–£25–
Assistant medical officer, class II	£325
Senior house officers	£260
House-physicians and house-surgeons	£156

These officers are provided with board, lodging, and laundry. Clinical assistants, who are non-resident, receive £105 a year, with meals when on duty. Vacancies in the higher grades are filled as far as possible by promotion from the existing staff. In addition, a large number of part-time consultants and specialists are employed in the various hospitals, as well as some whole-time non-resident specialists at a salary of £1400–£50–£1650. In addition to basic salary, medical staff receive the cost-of-living allowance applicable to all the council's professional grades of staff.

A central histological laboratory, as well as several group laboratories of the pathological service, serve a number of hospitals. Attached to the group laboratories are subsidiary laboratories situated in the various hospitals. Normally a medical staff of 25 is attached to these laboratories.

TEACHING FACILITIES

Courses in fever hospital administration for the diploma in public health, which were suspended during the war period, are now being held when required; refresher courses for medical officers released from H.M. Forces are held by arrangement with the British Postgraduate Medical Federation, University of London; other postgraduate facilities remain as they were. The British Postgraduate Medical School is at the Council's Hammersmith Hospital.

Increased use is being made of the Council's hospitals for teaching purposes. Arrangements have been made whereby maternity students have had training and experience in the maternity departments of the Council's general hospitals. The fever hospitals also provide for undergraduate instruction, and, when patients are available, for demonstrations in the diagnosis and treatment of smallpox for both undergraduate and postgraduate students. Students are resident during their course of instruction in some of the fever hospitals.

Most of the general hospitals are recognised training centres for candidates for the University of London rincipal town of each there is a large and well-ped hospital. In the smaller towns there are other ;als each in charge of a Sudanese doctor, and there ›me 400 dispensaries serving the still smaller towns ural areas. British medical inspectors are attached e main hospitals and may also supervise the areas iich they serve.

there are hardly any private practitioners in the ry all medical, surgical, gynæcological, and public-h and preventive work is carried out by members e service. There is also a varying amount of adminis-;e work to be done: medical boards must be held. school-children examined. Though it may be ble for work in the outstations to be arranged so a man who is keen either on medicine or on surgery be able to devote himself more to the branch he rs, all junior members of the service should be etent to undertake whatever comes their way. At ent most specialist appointments are filled by selec-from the more senior medical inspectors, and such notion, which depends on the occurrence of vacancies, re before 12 or more years of service. All specialist intments are held in the Khartoum-Omdurman , and the holders may be called upon to act also as rers and teachers in the Kitchener School of Medi-receiving fees, additional to their pay, for their ices in this capacity.

edical inspectors, if appointed on probation for ion, enter scale C5 at £E.720, unless a higher salary anted in recognition of age, experience, and qualifi-ons. Candidates over the age of 26½ who have war ice will have their starting salary fixed in such a as to give them credit for such service. Pay in C5 rises by 5 biennial increases to £E.1080, followed r 3 years at that rate by an increase to the maximum E.1200.

edical inspectors have prospects of promotion to s carrying a higher salary. At present these are:

irector	maximum	£E.1800
ssistant Director, Research ..	,,	£E.1500
ssistant Directors	,,	£E.1400
ecialist posts (in medicine, surgery, gynæcology, and ophthalmology)	maxima	£E.1750–1400
ovince Medical Inspectors.. ..	maximum	£E.1300
edical Officer of Health	,,	£E.1300

o income-tax is at present payable in the Sudan.

he probationary period is usually 2 years, after ch, subject to passing the prescribed Arabic examina-, and to the recommendation of the director, a medical ector is eligible for permission to join the pension me, which includes provision for widows and orphans. tributions are at the rate of 5% of salary, and retire-nt on pension is allowed at 48 if by that time 15 s' service has been completed. After 24 years' service pension is half of the mean of the last two years' ry. A gratuity is payable on voluntary retirement r 7 years' service.

rivate practice is permitted, provided that it does interfere with official duties, but except in a few of larger towns the opportunities for private practice few. A doctor is not allowed to charge private fees work performed in a Government hospital.

normal times leave of 90 days is granted every year r the first 18 months of service, and study leave may iven in addition for special purposes, but not usually l after 7 years' service has been completed. Full is drawn during leave periods and there are allow-s towards the cost of passages for officials and r families. No free quarters are provided. Govern-nt houses can usually be obtained on payment of and other charges. These vary according to the ion and the accommodation available but are usually veen £E.40 and £E.80 per annum.

he service provides good professional work combined an open-air life. Work may mean travelling on ection tours by rail, steamer, air, car, or animal sport. The climate varies from the hot dry Northern , through the central area which has a 3–4 months' y season, to the Southern zone, in which conditions ome increasingly tropical as the southern border of Sudan is approached. The general level of the ntry rises from 1200 feet at Khartoum to 2000 feet above the sea at Nimule, on the Uganda frontier. There are good opportunities for exercise—tennis, golf, and polo being the main afternoon games. There are swimming pools in the larger towns. In the Southern zone there is plenty of shooting and in many places very good fishing.

Applicants in the United Kingdom must be British born and should be under 30 years of age and preferably unmarried. An official is allowed to take a wife out to the Sudan after reaching the age of 27 or on completing 4 years' service, whichever happens first. Candidates selected for appointment will as a general rule be required to undergo a course of instruction at either the London or Liverpool School of Tropical Medicine, before sailing. The tuition fees are borne by the Government and a subsistence allowance of not less than £E.5 a week is paid during the course.

Candidates selected for appointment with the Sudan Government receive free transport from their home to their station in the Sudan. As appointment dates only from the date of their arrival at the Sudan frontier, they are given to cover the cost of the journey an allowance not less than the salary they would have earned if their appointment had dated from the date of embarkation for the Sudan. The conditions of service given here are liable to alteration in accordance with Government regulations. Further particulars and information about vacancies may be obtained from Dr. H. C. Squires, C.M.G., Consulting Physician to the Sudan Government, 93, Harley Street, London, W.1. (Telephone: Welbeck 3423.)

REGISTRATION

NO-ONE is a legally qualified medical practitioner unless his name appears on the Medical Register kept by the General Council of Medical Education and Registration of the United Kingdom. The council is a standardising body, ensuring that there is a prescribed minimum of medical education and examination requirements; it is also responsible for discipline within the profession.

The number of students admitted to medical schools in Great Britain and in Eire during the academic year 1944–45 was 2612, and for the year 1945–46, 2610.

NUMBERS OF UNDERGRADUATES AND PRACTITIONERS IN THE YEARS 1936–45

Year	Starting study in October	New graduates						Total no. in register on Dec. 31
		England	Scotland	Ireland	Colonial	Foreign	Total	
1936	2544	920	490	223	260	12	1905	59,010
1937	2297	1096	598	239	273	13	2214	60,163
1938	1735	1150	590	295	277	53	2365	61,420
1939	2623	1437	692	356	296	187	2968	63,410

1943	2426	1501	611	405	153*	862*	3532*	71,882*
1944	2612	1196	619	307	320*	529*	2971*	73,646*
1945	2610	1268	581	428	124*	265*	2666*	75,133*

* Including temporary registrations

The number of newly qualified in 1944 was 2122, and in 1945 was 2277. Since 1940 there have been 4258 temporary registrations in the colonial and foreign section of the register which are outside the stream of normal demand and supply; there were 322 such registrations in 1945. This form of registration ceased on Feb. 24, when temporary colonial registrations totalled 827, and temporary foreign registrations 3553.

Dr. F. M. Madwar, director of the malaria section of the Egyptian ministry of health, will speak at the Egyptian Institute, 4, Chesterfield Gardens, London, W.1, on Thursday, Sept. 5, at 6.30 P.M. His subject will be the Eradication of *Anopheles gambiæ* from Egypt.

Services Abroad

INDIAN MEDICAL SERVICE

ALL further recruitment to the Indian Medical Service has now ceased, and the government of India has made no final decision about the disposal of serving officers.

Recruitment to the Indian Army Medical Corps (I.A.M.C.) which is purely a military medical corps, will be *limited to Indian subjects, and will probably* be restricted to candidates holding a qualification recognised for registration under schedules 1 and 2 of the Medical Council of India. At present all officers serving in the I.A.M.C. hold temporary commissions.

WOMEN'S MEDICAL SERVICE FOR INDIA

Admission to the service is by selection in India and England. Appointment is open to English and Indian qualified women. Vacancies are few—usually only 3 or 4 in each year—and there is little recruitment from England. There is also a training reserve of qualified women recruited from Indian universities. Since the outbreak of war no members of the training reserve have been sent to England for postgraduate study, and leave out of India has also been restricted. Vacancies in the service are being filled by doctors in India as need arises, but *applications from Europeans holding higher medical* qualifications will be welcomed. The post of medical adviser in the United Kingdom is now held by Dr. Charlotte Houlton, C.B.E., S.P.G. House, 15, Tufton Street, London, S.W.1.

COLONIAL MEDICAL SERVICE

Vacancies in the Colonial Medical Service occur most often in tropical Africa and Malaya. Medical officers are required, to replace normal wastage and to provide staff for expansion; they must be British subjects and hold a medical qualification registrable in the United Kingdom. Candidates must have been born on or after Jan. 1, 1905, but, in addition, special contract terms are available for men up to the age of 45 or for younger candidates who would prefer to serve in the Colonies for a term of years rather than for their whole career.

Medical officers are appointed in the first instance for general service. There are opportunities for field investigation, and posts are filled from within the service for work in special branches of medicine and surgery and in public health. Medical research departments exist in the larger Colonies. Specialist appointments are usually reserved for officers holding higher appointments who have shown outstanding merit in a particular branch of medical practice. Opportunities to gain these qualifications will be made available whenever possible, and selected candidates may be required to attend a course of instruction in tropical medicine and hygiene before proceeding overseas, or else to attend such a course during their first leave period. Vacancies will occur in greater numbers in future for women with experience in gynæcological and maternity work, school public health, and child welfare.

Various Government medical departments employ about 700 European medical officers, including some 30 women, and about 1200 locally appointed medical officers. Depending upon the territory, such diseases as malaria, yaws, leprosy, sleeping sickness, plague, yellow fever, cholera, and other conditions associated with the tropics are encountered in addition to the usual *diseases experienced in any medical practice. An officer* in the Colonial Medical Service has special opportunities for the practice of preventive medicine, as well as opportunities for teaching and research.

The medical and health services will be considerably expanded in order to fulfil the schemes for public-health *development already planned. Full particulars of terms* and conditions of service may be obtained from the Director of Recruitment, Colonial Office, 15, Victoria Street, London, S.W.1.

SOUTHERN RHODESIAN MEDICAL SERVICE

The Government of Southern Rhodesia maintains a medical and public-health service with an establishment of 18 whole-time administrative specialist or public-health officers and 43 *Government medical officers.*

Rates of pay for the whole-time officers are:

	Annual Salary
Medical Director	£1800
2 Assistant Health Officers	£1350–£50–£15
School Medical Officer (man)	
Field Officer	
2 Radiologists	
2 Directors of Laboratories	
Government Pathologist	
Government Psychiatrist	
Medical Superintendent Mental Hospital	
Medical Superintendent Leprosy Hospital	
Assistant Medical Superintendent Mental Hospital	£1000–£50–£11
School Medical Officer (man)	£850–£30–£1
2 School Medical Officers (women)	

Government Medical Officers are graded as follows:

2 Senior Government Medical Officers	£1000–£50–£11
41 Government Medical Officers	£600–£25–£7

Whole-time medical officers and the two s Government medical officers are not permitted pri practice but are allowed consultant practice. G ment medical officers, except those stationed at Sal or Bulawayo, are allowed private practice, the val which varies from £100 per annum upwards, accor to the station. The duties of Government *officers include supervision of the* 18 Gov hospitals and numerous native clinics, and attendan on police, boarders in Government schools, and prison They also undertake medico-legal work and public-heal duties. Leave may be granted at the rate of one-eig of service, and may be taken in periods not exceedi 184 days at a time. Study leave may also be

After two years' service medical officers under t age of 45 can be appointed to the fixed establishme and contribute to a pensions' scheme. The retiring a is 60. On appointment Government medical officers usually stationed at Salisbury or Bulawayo, where t are not permitted private practice but are paid an a ance of £130 per annum in compensation. They are usu required to do relieving duties at various outstations a permanent vacancy occurs. Appointments in Gr Britain to the service are made by the High Commiss for Southern Rhodesia, Rhodesia House, 429, Str London, W.C.2, who will supply further details on requ

SUDAN MEDICAL SERVICE

The Sudan Medical Service aims at providing a co plete Health Service for the Sudanese people, Government officials, and for the Sudan Defence Fo The area of the Anglo-Egyptian Sudan is about a mi square miles—about the same size as British In and the total population is probably still less t 8,000,000. In accordance with the terms of the A Egyptian Agreement of January, 1899, the country under the joint protection of Great Britain and Egypt, its connexion with the British Government is through British Ambassador in Cairo and the British Foreign O

The country is embarking on a new period of deve ment in the educational, political, and economic sph and it is the policy of the Government that Suda shall have the opportunity of filling all Governm posts for which they may be fitted by person ability, and training. It is therefore important that *appointed British officials should be sympathetic* t policy, and should be ready and willing to play their *in assisting towards its achievement.*

The personnel of the Medical Service on the British consists at present of about 44 doctors, 32 nurses, some public-health inspectors and laboratory and *technicians.* On the Sudanese side there are more 80 doctors—trained at the Kitchener School of Med in Khartoum—some of whom have had postgrad experience in London, as well as public-health of and sanitary overseers, medical assistants in charg dispensaries, and a large number of hospital order *nurses, and midwives.*

The headquarters of the service are in Khartou and here, and in the adjacent town of Omdurman the central hospitals and specialist services, the Kitch School of Medicine, the Stack Laboratories, and wives' and Nurses' Training Schools. The project an entirely new hospital of over 400 beds for Khart has been initiated, and construction work will be star as soon as circumstances permit. Outside Khar the country is divided into seven main provinces, and l Institute of Public Health and Hygiene also courses for the diploma. conforming to the new ations; the next course begins in September.

YCHOLOGICAL MEDICINE.—Courses are at present in ance at many of the universities which used to grant loma in psychological medicine. The Royal College hysicians have recommended a five-year training psychiatric specialists, and the English Conjoint d has already issued new regulations for the diploma, h extend the course considerably. After June, 1947, idates will have to show that they have completed ast two and a half years of special study, including nonths' daily attendance in a recognised neurological rtment. eighteen months' whole-time experience in cognised institution for mental diseases, and six ths' whole-time study of child psychiatry and mental iency. These, moreover, are interim arrangements, ling the inception of a full five-years' curriculum udies and clinical training.

he universities of London, Durham, Leeds. Man- ter, Edinburgh, Belfast, Dublin (Trinity College), and (National University). and the English and Conjoint Boards normally offer diplomas in psycho- al medicine. The courses for the diplomas of ham, Leeds, and Belfast universities are at present ended. and at Edinburgh future courses will depend he demand and on the staff available.

he usual course for the D.P.M. is being held at dsley Hospital from June to December. In June July lectures and practical instruction are given on anatomy and physiology of the nervous system. and psychology, covering part I of the D.P.M. syllabus. m September to November inclusive the lectures h clinical demonstrations cover all aspects of psychiatry mental deficiency; and clinical instruction in psychi- y and neurology complying with the requirements of examining bodies is arranged. Lectures and demon- ations are also given on neuropathology. Clinical ruction is given at the Maudsley Hospital and is ilable also at St. Ebba's Hospital. Sutton Emergency spital, Banstead Hospital, and other London County ncil mental hospitals and institutions for mental iciency. Information can be obtained from the Dean, udsley Hospital Medical School, Denmark Hill, S.E.5.

he Tavistock Clinic has completed its move to manent quarters at 2. Beaumont Street. London. 1. The psychotherapy of both adults and children as patients, based on analytical concepts, which has racterised the clinic's activities in the past, is being eloped, and particular attention is being given to up psychotherapy. In addition to therapeutic work. clinic and the associated Tavistock Institute of man Relations are studying techniques in preventive chiatry. These include mothers' discussion groups, ection techniques. and techniques for improving erpersonal relations in school and industry and ilar psychological and sociological procedures.

The educational programme includes courses for chologists and social workers as well as doctors. e course for psychiatrists specialising in child psychi- y, arranged jointly with the Provisional National uncil for Mental Health, will be continued. Postgradu- instruction for doctors wishing to acquire experience the approach to psychotherapy in adult cases of rosis and allied behaviour disorders will be started October. 1946. The number of students accepted will limited and admission to the course will be by selection. me lectures in this course may be open to a wider dical audience. A weekly seminar in psychological dicine for general practitioners will also be held roughout the winter session if there is sufficient mand. Inquiries about training activities and fees ould be addressed to the Director of Studies, Tavistock inic, 2, Beaumont Street, London, W.1.

The Institute of Psycho-Analysis. 96. Gloucester ace. London. W.1. provides training in psycho-analytic eory and technique. The course is part-time and lasts out four years. It includes a personal analysis. atten- nce at lectures and seminars (held in the evenings), d clinical work done under supervision. Students are quired to obtain general psychiatric experience at other nics and hospitals. since the Institute does not set out teach all aspects of psychiatry. Completion of the course to the satisfaction of the training committee qualifies the student for election as an Associate Member of the British Psycho-Analytic Society. In addition to this main course designed for those intending to specialise, the Institute gives briefer courses from time to time on the application of the principles of psycho-analysis to medical problems. These are advertised in the medical press.

TROPICAL MEDICINE.—A diploma in tropical medicine is required by those seeking appointments in the tropics. Diplomas are granted by the English Conjoint Board: by Liverpool University jointly with the Liverpool School of Tropical Medicine, and by Edinburgh University. Courses are being held at Liverpool and Edinburgh. The London School of Hygiene and Tropical Medicine gives courses for doctors taking the Conjoint diploma. It is open to all qualified practitioners, but those not holding a qualification registrable in England should consult the secretary of the Conjoint Board, 8, Queen Square. London, W.C.1. The number of vacancies is limited, and those wishing to take the course should apply early to the Registrar, London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1.

Postgraduate Courses in Scotland

The EDINBURGH POSTGRADUATE BOARD FOR MEDICINE, which represents the university, and the Royal College of Physicians and the Royal College of Surgeons of Edinburgh, arranges programmes of graduate studies. Five general refresher courses, for general practitioners, each lasting a fortnight. have already been held. and two more are arranged for the long vacation. These are expected to run at regular intervals during the coming year: they are well attended. and not all those applying can find places. Classes in postgraduate surgery. lasting 10 weeks. have also been held, and some 280 surgeons have attended, but it is not intended to hold further short courses of this kind. Instead there will be two courses, each lasting 5 months. one beginning in October of this year and the next in March, 1947. Two courses in internal medicine, each lasting 10 weeks, have been held during the current session and have been attended by about 140 doctors. Each term the board arranges five lectures on subjects of wide biological interest: those for the forthcoming session are not yet announced, but those in the past session dealt with such subjects as the biology of death: uranium and neutrons; form and function; chemotherapy toxicity and chemical competition: and virus developments. Courses in midwifery, gynæcology. and pædiatrics, lasting a fortnight, have been arranged for general practitioners and have proved very popular.

The large size of the undergraduate school makes it difficult to provide detailed clinical teaching for postgraduates, but the board is considering ways of improving the position. The university and the Royal College of Surgeons have opened their libraries to those taking the longer postgraduate courses. The board has helped the dean of the faculty of medicine in placing candidates for posts under the demobilised medical officers scheme. Information may be had from the Acting Director of Studies. Postgraduate Board for Medicine, University New Buildings. Edinburgh.

GLASGOW UNIVERSITY has arranged for general practitioners a postgraduate course in obstetrics and pædiatrics, beginning in September and lasting a fortnight; and also general courses. also lasting a fortnight. to be arranged during the session according to demand. A course of lectures and clinical demonstrations on recent advances in internal medicine. lasting 7–8 weeks. will be held from October to December. and a similar course in surgery will run concurrently with it. Courses in diagnostic and therapeutic radiology. and probably in medical pædiatrics and some other specialties. will be arranged. Inquiries should be addressed to the Convenor, Committee on Postgraduate Medical Education. Glasgow University.

THE Home Secretary has appointed Dr. R. A. Young a member of the advisory committee on the administration of the Cruelty to Animals Act in place of the late Sir Farquhar Buzzard.

Postgraduate Education

In London

The University of London is expanding its provisions for postgraduate studies and has established the BRITISH POSTGRADUATE MEDICAL FEDERATION to develop and coördinate the educational facilities in London. Beginning with the university's postgraduate departments in general medicine, general surgery, obstetrics, and pathology at the Postgraduate Medical School and Hammersmith Hospital, the federation will include in the coming year the Institute of Child Health at Great Ormond Street, where a professorship has already been established, and the Institutes of Neurology at Queen's Square, of Laryngology and Otology at Gray's Inn Road and Golden Square, and an Ophthalmic Institute at Moorfields and the Central London Ophthalmic Hospitals. It is hoped to establish other institutes for teaching and research: in dermatology with the help of St. John's Hospital for Diseases of the Skin, in diseases of the chest with the Brompton Hospital, in genito-urinary diseases with St. Peter's and St. Paul's, in cardiology with the Heart Hospital, and in orthopædic surgery with the Royal National Orthopædic Hospital. Until the teaching schools at these hospitals can be staffed and equipped as university departments, they will collaborate with the federation and its constituent institutes.

The Maudsley Hospital already carries a university school, which will probably soon be brought into the federation as the Institute of Psychiatry.

The university has thus been able to make a beginning towards providing postgraduate education and training for specialists of an approved standard in medicine, surgery, and the major special branches, and graduates should apply to the Central Office of the Federation at 2, Gordon Square, London, W.C.1 (Tel.: Museum 6616), for details of opportunities and courses.

The central office plans to collect details of postgraduate facilities throughout the country and will shortly be able to provide up-to-date information of the opportunities available in London and elsewhere. The director and staff of the central office are always glad to advise graduates, who should arrange appointments in advance in order to avoid delays.

The accommodation at the institutes and associated schools and hospitals of the federation will not be sufficient for some time to meet the demands, especially in general medicine, general surgery, and obstetrics, so there must at first be some selection for the available places. Preference will be given during the coming year to ex-Service applicants and to graduates sponsored and recommended by their universities and governments. At all the institutes and schools associated with the federation courses of instruction and clinical work in wards and outpatient departments will be arranged, and the usual hospital appointments for clinical assistants, house-physicians and house-surgeons, and registrars will be available for the training of specialists.

At the undergraduate medical schools and teaching hospitals the usual hospital appointments provide postgraduate training of a high standard in all branches of medicine, but they are limited in number and vacancies are usually filled by their own graduates. Some of the medical schools arrange revision courses from time to time, suitable for candidates for higher degrees and diplomas, and a few places in these courses are available for selected graduates from other schools and from overseas.

For graduates who cannot be accommodated in the schools of the federation, or who do not require organised instruction and training, there are a number of other general and special hospitals where opportunities are available for attendance in wards and outpatient departments, and where short courses of lectures are arranged from time to time to meet temporary requirements, such as the preparation for specific examinations. The Fellowship of Medicine (see below) arrange courses of lectures of this kind, as need arises.

The central office of the federation will continue in the coming year to arrange intensive refresher courses lasting a fortnight for general practitioners released from the Forces, and as the demand from the ex-Service titioners diminishes, similar courses will be pr for other general practitioners, including those w under the National Health Insurance scheme. T courses will be held at voluntary and municipal ho other than those engaged in undergraduate tea and will be advertised in the medical press. the National Health Service is instituted other ty postgraduate education will be offered, to enable p practitioners to keep in closer touch with educat centres and teaching hospitals. Transitional ar ments in the coming year should give valuable exp for the future.

* * *

The FELLOWSHIP OF POSTGRADUATE MEDICINE, has a bureau at 1, Wimpole Street, London, W.1, p general information on postgraduate work, ar at various hospitals, courses of instruction which be classed under two main headings:

1. Weekend courses, occupying the whole of a S and Sunday, for general practitioners. These are in various general and special hospitals in such as general medicine and surgery, obstetrics and g cology, ear, nose, and throat conditions, ophthalm children's diseases, and rheumatic diseases.
2. Short clinical courses for candidates for the M.R.C.P. F.R.C.S. (final) given shortly before the examination

Twice a year revision courses in anæsthetics arranged in Oxford and in London; also lecture-dem strations for primary F.R.C.S. candidates, and occas courses for M.R.C.O.G. candidates and D.C.H. candid

Other courses are arranged from time to tim proctology and urology. It is hoped to add to t number and variety of courses as facilities permit.

Some London Courses

SURGERY.—The Royal College of Surgeons arranged a course of surgical lectures and demonstra to be delivered at the college in Lincoln's Inn F London, W.C.2, at 5 P.M. daily, between Oct. 21 Nov. 6. A course of lectures in anatomy, applied phy logy, and pathology will be given between Sept. 2 Oct. 18. Fellows and members of the college will admitted without charge to either series of lectures must apply for a card of admission. Similar cour lectures will be held in the early part of next These courses of lectures must not be regarded as specially arranged for the final and primary fell examinations: but they are so planned as to be h to candidates, and also to practising surgeons, by d with the practical application of recent advance

The college maintains a library, museums laboratories for the use of medical graduates fro parts of the world. Fellows and members enjoy facilities by right, but they have also been made on suitable introduction, to other graduates of med and to undergraduates.

The Arris and Gale and the Hunterian Lectures p opportunities for the presentation of original w anatomy, physiology, pathology, and surgery. college awards several prizes for meritorious w well as many fellowships for those who desire to en in practical work in the museum and laboratories devote some time to research.

PUBLIC HEALTH.—Most university courses in p health have now been revived. Before the war a was granted by all the British universities except Ox Cambridge, and Sheffield. New requirements by G.M.C. have caused universities to revise the cour this examination, which is now taken in two parts first leading to a certificate in public health (C.P. taken after three months' work, and the second to diploma. The London School of Hygiene and Trop Medicine offers a course beginning in October and la nine months, and designed primarily for those inte to seek posts as medical officers of health. All vaca for the full course for the diploma have been filled. there is a waiting-list, but in view of the developmen and subdivision of medical work in the public-hea service, some places in the course for the certific have been reserved for doctors who intend to under public-health work other than that of a M.O.H.

cation, and the B.M.S.A. has organised several iange schemes, mostly reciprocal, with such countries Sweden, Denmark, Czechoslovakia, and Switzerland. eral parties of foreign students have already arrived his country, and many students from Great Britain spending their summer vacations abroad, studying lical methods and at the same time having good days. An appeal for medical books for Czech students ught extremely good results.

he same peripatetic tendency has been seen at home year. A clinical conference, organised by the associa- i in conjunction with the medical students' represen- ve council of the University of Durham, was held at vcastle-on-Tyne in July. It was attended by repre- tatives from the northern region of the B.M.S.A., l observers from Scotland and Ireland were also sent. This conference lasted four days and included ical instruction and lectures in the Royal Victoria irmary as well as several visits to other institutions l places of interest, notably to two miners' reablement tres. Apart from formal work, the conference e ample opportunity for the various delegates to et each other and to exchange information and nions.

t Easter Mr. J. J. A. Reid, B.SC., the president of association, visited the Sanatorium des Étudiants France, near Grenoble, and studied the French dents' anti-tuberculosis scheme, which is very good. has prepared a report to be considered by the B.M.S.A. l the National Union of Students, in the hope that ne similar plan may be possible in Great Britain. anwhile, recent advances in student health work being investigated.

The Glasgow branch of the association started a blood- nor campaign with sessions at times convenient to idents, and obtained 180 pints of blood for the local nsfusion service, which needed it badly. This scheme to be expanded in the next few months. This branch s also established, after investigating the point with Ministries concerned, that clinical clerks are not ble to health and unemployment insurance contribu- ns—an important point, since students had been made pay contributions while clerking in some Glasgow and strict hospitals. The Durham branch has produced report on the question of compulsory and non- mpulsory lectures.

The film secretary of the association has reported on e position of medical films in the past and present, d their probable place in future teaching. Four edical schools are now producing their own films.

The use of wall-newspapers is spreading in many hools, and a panel of lecturers is being prepared for e use of medical-student societies. The report on the st of medical education is to be published this year. Meetings, visits, and discussions have been arranged in e various regions, and the B.M.S.A. is in an even better sition to help and serve the needs of medical students an it was a year ago.

FECTIOUS DISEASE IN ENGLAND AND WALES

WEEK ENDED AUGUST 17

Notifications.—Smallpox, 0; scarlet fever, 690; ooping-cough, 2097; diphtheria, 251; paratyphoid, typhoid, 53 (19 in Cardiganshire); measles (exclud- g rubella), 2712; pneumonia (primary or influenzal), 0; cerebrospinal fever, 47; poliomyelitis, 33; polio- cephalitis, 1; encephalitis lethargica, 1; dysentery, ; puerperal pyrexia, 136; ophthalmia neonatorum. No case of cholera, plague, or typhus was notified ring the week.

Deaths.—In 126 great towns there were 4 (0) deaths om enteric fever, 1 (0) from scarlet fever, 6 (3) from easles, 5 (0) from whooping-cough, 3 (0) from diph- eria, 39 (2) from diarrhœa and enteritis under two ars, and 6 (0) from influenza. The figures in parentheses e those for London itself.

The number of stillbirths notified during the week was 4 (corresponding to a rate of 31 per thousand total rths), including 43 in London.

TYPHOID IN WALES.—Up to August 26 there have been further secondary cases of typhoid in Aberystwyth d district, making a total of 134, with 4 deaths.

In England Now

A Running Commentary by Peripatetic Correspondents

I ASKED our professor of anatomy what his views were on the reform of the medical curriculum in his own subject. He agreed that much dead wood should be cut out of the large forest of anatomical detail, but I found that he was bent on planting several new saplings, such as genetics, embryology, neuro-anatomy, and histology in his domain. I remarked that the last two were often taught by physiologists, but he sniffed and said that they were better taught by anatomists. I then changed my ground. "Do you really think it necessary for the medical student who is to become a general practitioner to dissect the whole human body?" I asked. He looked at me as if I had suddenly taken leave of my senses. "Of course," he replied, "how else can he obtain the necessary knowledge for the practice of his profession?" "As a matter of fact he does not now obtain that knowledge," I answered, "or if he obtains it he does not retain it." "What do you mean by that?" he asked almost angrily. "Simply this," I said, "that the medical student by the time he is ready to go in for his final examination in surgery has, as a rule, forgotten most of the important data which he was supposed to learn by dissection." The professor doubted this, so I invited him to the next surgical anatomy examination for the qualifying degree in surgery to hear and see for himself the abysmal degree of ignorance of anatomy revealed there. I doubt if he will come, and if he came I doubt whether he would draw from the evidence the same conclusions which I would draw.

Every examiner in surgery will probably agree with me that most students up for their final do not know the basic facts of anatomy. The only way in which these facts can be taught is by continuous repetition. Such a method of teaching is dull for the teacher, and it is quite understandable that many may lay undue stress on the (to them) more interesting problems of embryology and neurology which should really be dealt with in an honours class.

I doubt very much if the dissection of the whole body should be compulsory for the ordinary qualifying examination. Certainly the arm and the lower limb should be dissected, but if the student has a sound knowledge of the skeleton he should acquire sufficient knowledge of the abdomen, chest, and cranium at demonstrations in the dissecting-room and the post-mortem room. Anyway, I prophesy that circumstances will soon compel the limitation of anatomical dissection. When the new social security and health Bills become law where will the anatomical subjects come from?

* * *

Why my thoughts went back to that ancient half-forgotten figure of a physician, Verrily Namlos, I do not know. But I had been dipping into a new History of Medicine which someone had given me, and I was perhaps keenly conscious of the great cloud of witnesses whose names adorn our profession. He was not highly thought of in his own day. His was one of the obscurer medical schools—St. Gallipot's, then almost hidden in a retiring old-world corner of the City, on the south-west side of Galen's Gardens. He wrote little. Comparatively early in his career he ceased to speak at official medical meetings, save on the rarest of occasions. Although he became a fellow of the College, he never held high office, and when he died the president was hard put to find anything original to say about him in the annual obituary oration.

I once heard him claimed as probably the greatest medical educationist of all time—and that years ago, before the modern debasement of the currency of words. Yet nowadays who remembers him, save as a name to which there clings a faint aroma of distinction, elusive and ill defined? Even the little biography, put together some years after his death by a few of his old students, is hardly ever read; the copies which, for curiosity, I have hunted out in various medical libraries were covered with the dust of years. My own precious copy I picked up, long before the war, in the sixpenny box at Mustie's bookshop in Physicians' Walk, its brown calf covers tattered and loose at the hinges, its old-fashioned pages

STRASBOURG AND MANCHESTER

A PROPOSED LIAISON

ROBERT PLATT
M.D. Sheff., F.R.C.P.
PROFESSOR OF MEDICINE IN THE UNIVERSITY OF MANCHESTER

THE idea of a close liaison between the universities of Manchester and Strasbourg originated from some of the Manchester staff and students, and a party of students has already made a visit to the proposed sister university. The University of Strasbourg then invited Manchester to send three delegates from their staff, and on July 4 the professors of French, cryptogamic botany, and medicine (representing three major faculties) set off from Ringway airport.

We were in Paris in 2½ hours where we were entertained to lunch by representatives of the French Ministry of Education. We travelled to Strasbourg the same evening, and during our stay there worked independently, each one being shown round and entertained by members of his own faculty.

The medical school is accommodated in a series of institutes, in close touch with the Hôpital Civil; in fact, the various departments of anatomy, physiology, and pathology, though in separate buildings, are in the same grounds as the clinics of the hospital. There are 2200 beds and about 800 medical students, and it would be no exaggeration to say that equivalent accommodation does not exist at any British medical school. Strasbourg is recovering rapidly from damage by air-raids and disorganisation due to German occupation, and most departments are already in full action. One of the biggest difficulties at present is the lack of the British and American literature of the war years. This is being gradually made up, partly by the use of microfilms; but reprints of important British papers would be very welcome.

We were there primarily to explore the possibilities of exchange of students or postgraduates, and to decide whether it was possible to arrange visits and lectures by members of staff. It was therefore important to find out in what respect the medical curriculum differed from our own.

The normal medical course is six years and is much the same as ours, with two major exceptions. Students do elementary clinical work from the first year onwards, in addition to their other studies; and in the fourth or fifth year some of the students—usually not more than 10—are selected by examination to become interns. These then follow a different course and do not qualify until they have done another four years while actually resident in the hospital. During this time they change at intervals from one clinic to another (medical, surgical, pædiatric, &c.).

This selection of the élite for a special course is highly desirable, though possibly the selection is not made at the best time. I would prefer to see in our own universities an honours school of medicine in which selected students would learn more organic chemistry, would spend an extra year at least in physiology, and pursue a more advanced course of study with resident experience in clinical subjects. This would be one solution of the old conflict between the desire to give the best students a really intelligent education, and the need to provide a basic technical training for the average. Such subjects as the history of medicine could be introduced into the honours course without it being necessary to answer the question "What use are they?"

An interesting experiment at Strasbourg is the appointment, recently made, of a professor of biology in the medical faculty, whose course of instruction will replace the usually ill-adapted studies in botany and zoo shared by medical and science students. The cl are organised on the Continental system with a director for every clinic or service, each of which comprise as many as 250 beds. On such a unit there be perhaps three assistants who are experienced ph cians or surgeons allowed to engage in private prac There is also a chef de clinique who would corresp with our resident medical officer. He has an assis and the remaining residents are the intern students alr referred to. Each clinic has its laboratories and labo workers, and full facilities such as X-ray departm electrocardiograph, or operating-theatres as necessar

It is easy to see advantages and disadvantag both our system and theirs. Owing to the differ in the medical course there are difficulties in arra exchanges between the two universities, but it is l that, at the very least, vacation visits can be arra during the summer months. We hope shortly to h a return visit from our colleagues at Strasbourg, wh such questions can be further discussed. Often in the past lip-service has been given to the notion of a cl liaison between the cultural interests of Britain and th Continent, but this beginning seems likely to lead t something more concrete, a true bond between th universities, sponsored and encouraged by the authoriti on both sides.

Throughout our stay in Strasbourg we were the gues of the university, and in our many intimate discussio often in not too good French or English—we caug glimpses of what some of our colleagues had been throu Several had been in concentration-camps, many h relatives who had never returned. This brief note giv no hint of the truly fraternal feeling evident during t visit. The meeting was like a reunion of members of a family whom long years of war had separated.

BRITISH MEDICAL STUDENTS' ASSOCIATIO

THE British Medical Students' Association, f during the recent war, has extended its activities co siderably in the first post-war year, both in the natio and in the international fields.

Thanks to relaxation in paper control, the associati has been able to publish a national journal for medi students this year. The first number, a special inte national edition, is already on sale, and contains a account of the new world student organisation whi is now being born in Prague; the international secretar of the association has been several times to Prague t help with the antenatal care of this hopeful child. H report on some medical and social aspects of Czech slovakia also appears in the first issue of the journ The second number will be published in October, an the journal will afterwards appear quarterly, and wi be available in almost all the universities and medi schools of Great Britain and Ireland. It will cove wide range of technical and non-technical subjects, and will contain contributions from both students or eminent seniors in the profession. This journal, it hoped, will bring students from all parts of the countr into touch with one another.

The National Health Service Bill presented seve problems for the B.M.S.A. It was clearly the duty of the association to try to discover the opinions of th medical students of the country on this important issu but to have convened a special representative meetin in London to discuss it would have been too expensiv for the constituent organisations. A questionnaire wa therefore circulated to every medical school, includin the few which are not members of the B.M.S.A., and wa answered by a satisfactory proportion of student Results were analysed by the British Institute of Publ Opinion, to whom the association is also indebted f advice on the questions to be asked. The final results are to be drawn up in the form of a report which will be presented to the Minister of Health.

Student exchange with foreign countries has long been recognised as a valuable part of teaching and

Notes and News

THE CAPITATION FEE

LAST Saturday the Ministry of Health announced that capitation fee payable to doctors for each insured person their lists under the National Health Insurance Acts has n increased from 10*s*. 6*d*. to 12*s*. 6*d*. with effect from Jan. 1, 6. Accumulated back payments will be made in the near ure—if possible at the end of September.

he extra cost of the new fee during the period between . 1, 1946, and April 1, 1948, when the National Health vice will come into operation, will be about £4,500,000. cussions on the subject between the Ministry and the urance Acts Committee were summarised in our issue of gust 3 (p. 166).

THE STUDENTS' JOURNAL

HE development, in a few years, of the British Medical idents' Association from a relatively sluggish section of National Union of Students has been almost as remarkable the metamorphosis of a caterpillar. This year the associa- n has published the first issue of the *British Medical idents' Journal*, an international number, well written and duced; and illustrated by good photographs. It tells the story the first World Student Congress to be held since the war.

"On the 17th November, 1939, the Charles University in Prague was closed by the German authorities, nine heads of he students' organisation were shot, and a large proportion of the male student population was thereafter thrown into concentration camps or sent to forced labour inside Germany."

fugee students and British students decided together that day should be remembered as International Students' y; and the first celebration of it was held in Prague last ar. The great welcome given to students of all countries o went to this gathering and the plans made for their cussions and for their entertainment evidently moved eply those who attended, and must have done much to ablish that sense of fellowship on which the peoples of the rld must rely for a safe and constructive future.

This journal makes impressive reading.

PATENT-LAW REFORM

THE Joint Chemical Committee on Patents submitted a emorandum to the Board of Trade Patents Committee in ptember, 1944; some aspects of the views therein contained, pecially in relation to chemical manufacture, the exploitation medical discoveries, and the preservation of secrecy, were cussed here at the time (*Lancet*, 1944, ii, 542). In June of is year the Joint Committee produced a second memoran- m, covering wider considerations of patent-law reform. e two documents have now been reprinted in a single volume blished by the Association of British Chemical Manu- cturers (3*s*. post free). Some of the recommendations have eady found favour and are included in the *Second Interim* port of the Departmental Committee (Cmd. 6789). Patent r is repulsively technical, but those who understand these ysteries will find much to interest them in the new publication.

To take a casual instance of the complication of the law, the kward interpretation of words like "manner of manu- cture" has been illustrated by the recent discovery of werful insecticides. Hitherto little more than chemical riosities, certain substances have been found to possess eat industrial significance. Being *new*, the discoveries ould confer patentable "subject matter" in their novel dustrial application as insecticides. The application is the anufacture, but, since the substance was already known, the anufacture lacks novelty and is unpatentable. Killing sects is not manufacture. The only patent cover obtainable for some novel composition containing the active substance in other words, for the mixing of the substance with a luent. So what is intrinsically unpatentable becomes tentable by the addition of a non-inventive stage. The anufacture would be patentable, if novel; the mixing of some mmon diluent is relied upon to provide the necessary velty. In Holland and the United States, as in pre-war ermany, it appears, the use of substances as insecticides has en patentable.

Two matters in the memorandum may be mentioned as of terest to the medical profession. Under section 38A of the tents Act, compulsory licences may be granted in respect patents relating to food and medicine. No great use has en made of the powers in the section, though they may have indirectly inclined pharmaceutical manufacturers to grant licences by voluntary agreement. The Joint Committee observe that difficulty has occurred in interpreting section 38A because the section deals both with chemical inventions and also with inventions relating to food and medicine. They suggest that when the Act is rewritten the section should be split and the two classes of invention separately treated.

Secondly they note that the royal prerogative reserved to the Crown by section 97 has lately been exercised to refuse a patent concerning a device for calculating the "safe periods" for marital intercourse, and that under section 75 patents have been refused for contraceptive chemicals and devices. The Act at present embodies this jurisdiction to refuse recognition to patents "contrary to law or morality." The Joint Committee think that the words "or morality" might be deleted from the statute. Such inventions, they say, may be useful contributions to medical knowledge and it is difficult today to regard them as necessarily contrary to public morals. "Many patented inventions are capable of abuse with much more devastating results, and we urge that patent specifications are a form of literature which should be regarded as 'technical' equally with the *Lancet* and the *British Medical Journal*."

CENSUS OF HOSPITAL CASES

THE Glasgow Bureau of Health and Sickness Records, of which Prof. T. Ferguson is chairman, is undertaking a census of all hospital-treated sickness occurring among people domiciled in the county of Stirling (including the "large burghs" of Falkirk and Stirling) during the year beginning on Oct. 1. The intention is to cover all kinds of sickness, including mental illness, and to collect information about Stirlingshire cases not merely from hospitals within their area but also from city and other hospitals to which patients in the county commonly go for treatment. The aim is to get a fairly complete picture of the nature and extent of hospital-treated sickness in what is a fairly typical and representative Scottish county area. The information thus obtained may well point the way to useful administrative action.

BRITISH BOOKS ON SHOW IN SWITZERLAND

AN exhibition of British books, old and modern, general and technical, will be opened in Berne on Sept. 3, and will later be shown in Bâle, Zürich, Geneva, and Lausanne. The first exhibit is an original leaf of the *Chronicles of England*, printed by Caxton in 1480. A separate section will be devoted to the periodical press. The display, devised by the British Council, follows four months after an exhibition of Swiss books in London.

INVALID AND VOIDABLE MARRIAGES

"MARRIAGES are also void in the case of certain diseases. Information about these should be sought from a reliable medical man." Reading this statement in a book, a clergyman asks us for further facts.

There are certain requisites for a valid marriage, and if any of these is absent the marriage is void ab initio: (1) both parties must be over sixteen years of age; (2) both parties must be mentally capable of understanding the nature of the contract; (3) the parties must not be within the prohibited degrees of relationship; (4) both parties must freely consent, consent obtained by duress or force being void, but not consent obtained by fraud; (5) there must not be an already subsisting marriage which is valid; and (6) the ceremony must be in proper form.

It will be seen that there is no provision for invalidity on the grounds of disease, apart from (2) above. There are certain grounds upon which a marriage is *voidable*, but this does not mean that the marriage was originally unlawful, and indeed in all these cases it is entirely at the option of the party aggrieved whether the marriage is avoided or not. Even in the case of venereal disease the petitioner must satisfy the court that he or she was unaware of it at the time of the marriage and refused intercourse on learning of it (Matrimonial Causes Act, 1937). The clear implication is therefore that such disease is no bar to a valid marriage.

The grounds of voidability are (1) incapacity due to incurable physical mental or moral disability; (2) wilful refusal to consummate; (3) unsound mind or mental deficiency of one party of which the other was ignorant at the time of the marriage; (4) communicable venereal disease subject to the proviso above mentioned; (5) pregnancy of the respondent by another man at the time of marriage. In all these cases the marriage is valid until avoided, and in the last three petition must be made within a year of marriage.

badly foxed. You must get hold of a copy if you would see what he made of medical teaching; for there is a quality about it which defies summary, or even quotation. It is a book to be read as a whole, to be marked, learned, and inwardly digested. But I *cannot forbear* to pass on (as a kind of aperitif) an illuminating confession made in later life to one of his biographers. In my view it can stand as the perfect background to the man.

At the outset of his career as a physician, on his appointment to the staff of his teaching hospital, Namlos took a tramping holiday, alone, in the Lakes, with the purpose of getting straight in his mind what medical teaching and education really meant. He came to realise that there were three things he must at all costs avoid—three "temptations of the Devil," as he put it. The first was to teach medicine by rote, reducing it to an easily memorised system of tips, classifications, short cuts, synopses, unrelated facts. To do this would doubtless bring him popularity as a "good teacher," and there would be plenty to join his classes for such *examination drill.* He saw that to yield to this, the most insidious of temptations for the medical teacher, would be to offer his students stones instead of bread. He enjoyed contact with students, and a popular following would have given him much pleasure; but it was not in his character *to seek popularity, and he never achieved it.*

Of much less appeal to a man of his type was the temptation of trying to build up a reputation of being gifted with mysterious clinical powers. Some teachers hoodwink themselves, and for a time their students, into the belief that there are secrets of medicine which they, and only they, possess. They almost come to feel that, wizards themselves, they may graciously pass on the magic tricks to their initiates. Namlos could only chuckle at the thought of his ever joining such a magicians' circle; he would be found out at once, by the greenest novice among his clinical clerks.

He admits that for a brief period Satan nearly got under his guard with a third temptation, by sketching a picture of the rôle of the great man in medicine—vistas of leadership and opportunity, of academic and public honours, *which in their turn would lead to ever-widening* influence among the great and powerful. So, through him, might medicine become greater, and his own name be remembered down the ages as a benefactor of mankind. A devilishly appealing picture, indeed! But as he came down the hillside, one darkening afternoon, to the little farm where he was staying, and to the simple rugged souls with whom he was at home, he knew that for him this sort of activity and achievement would be but vanity. One of Sydenham's *Observationes Medicæ* came to his mind: "There is but one sort of true wisdom, to take a true measure of one's self and not throw dust in one's own eyes."

I should have enjoyed writing his obituary notice. I would like to have written of him what was said, years later, of an Oxford teacher: "He loved great things, *and thought little of himself; desiring neither fame nor* influence, he won the devotion of men, and was a power in their lives; and seeking no disciples, he taught to many the greatness of the world and of man's mind."

* * *

Correspondents, both peripatetic and honorary, have recently complained about the F.R.C.S. and D.N.Y. examinations; so let me, among the trumpetings of these great men, insert a diffident whimper about the M.B. This exam is near and very dear to me—but it is not nearly near enough, that is the trouble. The feeble-minded among us *are referred for three months (three,* mark you) but we have to wait six for the next opportunity. The senior members of the profession, who decide these things, looking back on their century of service, may well argue that three months is little in a man's life, but let the senior member break his glasses in July and hear that they can't be repaired till October. My friends, though commiserating with me last April, were envious, too. "Think of it," they said, "the whole summer and nothing to do but revise for half of one part." I was pleased as well as annoyed. I could read all those Penguins I had bought and never opened, I could go to the theatre as often as a civilised man ought, I could read diffusely and indiscriminately among the textbooks instead of looking up "the things they ask." But my friends dash off parts of the Conjoint and qualify all round me. "Utility Doctor!" I say with scorn, the bitter because I envy them. I could do the same of co take the whole Conjoint at once, but forty-odd gu more than I can raise, in addition to M.B. fees, f *diploma I don't really want.*

Then hanging over me throughout this lazy summ the possibility that I might fail next time. At ni dream that I get Snodgrass, who is notorious for spe a whole viva plugging away at some obscure detail. breakfast I know that in six months I can learn so that even Snodgrass won't be able to catch me. By t time I break for coffee in the morning I know that do nothing but this subject, which has never inter me anyway, for six months I shall go mad. Per if I were a Good Type I would be sufficiently inter in every specialty of medicine to immerse my se any one of them for half a year.

Why not an M.B. exam every three months, like t Conjoint? Perhaps because far fewer students w take the latter (about 40% of students from Lo schools register on a diploma and take a degree la If only somebody would do something about Goodenough report, all would be well. But while plann smacks of Mr. Bevan, and free competition between t licensing bodies is in Bad Taste (and it lowers the pric *but we won't mention that)* what is a poor student to

Oh the London Deans,
The Provincial Deans;
Oh the deans brought up on medicated beans;
Oh the tall deans,
Short deans,
Much too fond of sport deans;
Oh the deans with the means to support deans;
Oh the long-nosed deans;
Oh the pin-toed deans:
Oh the stiff-necked, the bottle-necked
Oh the duff-stuffing, snuff-puffing, dottle-de
Deans.

* * *

One of the snags of the Army is the lack of resp *sibility—it is far too easy to* "pass the buck." E the R.A.M.C. are not exempt. Specialist service a too easily available—far too many patients are se for specialist opinion or for admission to hospital with being examined properly, if at all. This lack of the se of responsibility particularly applies to those who h never been in civilian practice. Whether a M.O. does job well or not makes no difference to his pay or pro tion prospects. Unless he is moved from within to d his best for his patients, and unless he feels a sens responsibility for their welfare, he will be a bad doc Unfortunately, no legislation can remove this de from an organised medical service, where there is struggle for existence and no incentive to work ha Presumably the solution is the more careful selec of candidates for medicine?

* * *

I wonder when the scientific mind will get to work our birthdays. Probably they are fairly well down t list, but I fear the day is inevitable when the cold st of common sense will wash away much of the hap hazardness of this event. For instance, I turned up March 2, 1923. On the icy pavement of the pr winter my mother probably had several shots at prec tating my arrival at times when I was just getting p the lizard stage. When the time did come, the do was messing around in his car in the last snow *before spring and gave neither* of us a helping h My father saved up his last winter cold for me, so th I was grappling with a bronchopneumonia whe should have been devoting my leisure to integrating personality.

I should imagine birthdays will be restricted to Ju July, and August, probably largely by the prohibit of contraceptives in September, October, and Novem and their free supply for the rest of the year. Child will be unanimously in favour as it safeguards them fr the tragedy of a birthday next door to Christmas, wh presents and parties are usually miserably telescop Parents will put up only sporadic resistance. Th organised fight will come from the vested interests: th contraceptive manufacturers struggling for their priva enterprise and obstetricians for their summer holidays.

Notes and News

THE CAPITATION FEE

AST Saturday the Ministry of Health announced that capitation fee payable to doctors for each insured person heir lists under the National Health Insurance Acts has ı increased from 10*s*. 6*d*. to 12*s*. 6*d*. with effect from Jan. 1, . Accumulated back payments will be made in the near re—if possible at the end of September.

he extra cost of the new fee during the period between . 1, 1946, and April 1, 1948, when the National Health rice will come into operation, will be about £4,500,000. ussions on the subject between the Ministry and the rance Acts Committee were summarised in our issue of ust 3 (p. 166).

THE STUDENTS' JOURNAL

HE development, in a few years, of the British Medical dents' Association from a relatively sluggish section of National Union of Students has been almost as remarkable he metamorphosis of a caterpillar. This year the associa- has published the first issue of the *British Medical dents' Journal*, an international number, well written and duced, and illustrated by good photographs. It tells the story he first World Student Congress to be held since the war.

" On the 17th November, 1939, the Charles University in rague was closed by the German authorities, nine heads of e students' organisation were shot, and a large proportion f the male student population was thereafter thrown into oncentration camps or sent to forced labour inside ermany."

ugee students and British students decided together that day should be remembered as International Students' ; and the first celebration of it was held in Prague last r. The great welcome given to students of all countries went to this gathering and the plans made for their ussions and for their entertainment evidently moved ply those who attended, and must have done much to ablish that sense of fellowship on which the peoples of the ld must rely for a safe and constructive future.

his journal makes impressive reading.

PATENT-LAW REFORM

HE Joint Chemical Committee on Patents submitted a morandum to the Board of Trade Patents Committee in tember, 1944; some aspects of the views therein contained, ecially in relation to chemical manufacture, the exploitation medical discoveries, and the preservation of secrecy, were cussed here at the time (*Lancet*, 1944, ii, 542). In June of s year the Joint Committee produced a second memoran- n, covering wider considerations of patent-law reform. e two documents have now been reprinted in a single volume lished by the Association of British Chemical Manu- turers (3*s*. post free). Some of the recommendations have eady found favour and are included in the Second Interim port of the Departmental Committee (Cmd. 6789). Patent is repulsively technical, but those who understand these steries will find much to interest them in the new publication.

o take a casual instance of the complication of the law, the kward interpretation of words like "manner of manu- ture" has been illustrated by the recent discovery of erful insecticides. Hitherto little more than chemical iosities, certain substances have been found to possess at industrial significance. Being new, the discoveries uld confer patentable "subject matter" in their novel lustrial application as insecticides. The application is the nufacture, but, since the substance was already known, the nufacture lacks novelty and is unpatentable. Killing ects is not manufacture. The only patent cover obtainable or some novel composition containing the active substance n other words, for the mixing of the substance with a ent. So what is intrinsically unpatentable becomes entable by the addition of a non-inventive stage. The nufacture would be patentable, if novel; the mixing of some nmon diluent is relied upon to provide the necessary elty. In Holland and the United States, as in pre-war rmany, it appears, the use of substances as insecticides has n patentable.

wo matters in the memorandum may be mentioned as of erest to the medical profession. Under section 38A of the tents Act, compulsory licences may be granted in respect patents relating to food and medicine. No great use has n made of the powers in the section, though they may have indirectly inclined pharmaceutical manufacturers to grant licences by voluntary agreement. The Joint Committee observe that difficulty has occurred in interpreting section 38A because the section deals both with chemical inventions and also with inventions relating to food and medicine. They suggest that when the Act is rewritten the section should be split and the two classes of invention separately treated.

Secondly they note that the royal prerogative reserved to the Crown by section 97 has lately been exercised to refuse a patent concerning a device for calculating the "safe periods" for marital intercourse, and that under section 75 patents have been refused for contraceptive chemicals and devices. The Act at present embodies this jurisdiction to refuse recognition to patents "contrary to law or morality." The Joint Committee think that the words "or morality" might be deleted from the statute. Such inventions, they say, may be useful contributions to medical knowledge and it is difficult today to regard them as necessarily contrary to public morals. "Many patented inventions are capable of abuse with much more devastating results, and we urge that patent specifications are a form of literature which should be regarded as 'technical' equally with the *Lancet* and the *British Medical Journal*."

CENSUS OF HOSPITAL CASES

THE Glasgow Bureau of Health and Sickness Records, of which Prof. T. Ferguson is chairman, is undertaking a census of all hospital-treated sickness occurring among people domiciled in the county of Stirling (including the "large burghs" of Falkirk and Stirling) during the year beginning on Oct. 1. The intention is to cover all kinds of sickness, including mental illness, and to collect information about Stirlingshire cases not merely from hospitals within their area but also from city and other hospitals to which patients in the county commonly go for treatment. The aim is to get a fairly complete picture of the nature and extent of hospital-treated sickness in what is a fairly typical and representative Scottish county area. The information thus obtained may well point the way to useful administrative action.

BRITISH BOOKS ON SHOW IN SWITZERLAND

AN exhibition of British books, old and modern, general and technical, will be opened in Berne on Sept. 3, and will later be shown in Bâle, Zürich, Geneva, and Lausanne. The first exhibit is an original leaf of the *Chronicles of England*, printed by Caxton in 1480. A separate section will be devoted to the periodical press. The display, devised by the British Council, follows four months after an exhibition of Swiss books in London.

INVALID AND VOIDABLE MARRIAGES

"MARRIAGES are also void in the case of certain diseases. Information about these should be sought from a reliable medical man." Reading this statement in a book, a clergyman asks us for further facts.

There are certain requisites for a valid marriage, and if any of these is absent the marriage is void ab initio: (1) both parties must be over sixteen years of age; (2) both parties must be mentally capable of understanding the nature of the contract; (3) the parties must not be within the prohibited degrees of relationship; (4) both parties must freely consent, consent obtained by duress or force being void, but not consent obtained by fraud; (5) there must not be an already subsisting marriage which is valid; and (6) the ceremony must be in proper form.

It will be seen that there is no provision for invalidity on the grounds of disease, apart from (2) above. There are certain grounds upon which a marriage is *voidable*, but this does not mean that the marriage was originally unlawful, and indeed in all these cases it is entirely at the option of the party aggrieved whether the marriage is avoided or not. Even in the case of venereal disease the petitioner must satisfy the court that he or she was unaware of it at the time of the marriage and refused intercourse on learning of it (Matrimonial Causes Act, 1937). The clear implication is therefore that such disease is no bar to a valid marriage.

The grounds of voidability are (1) incapacity due to incurable physical mental or moral disability; (2) wilful refusal to consummate; (3) unsound mind or mental deficiency of one party of which the other was ignorant at the time of the marriage; (4) communicable venereal disease subject to the proviso above mentioned; (5) pregnancy of the respondent by another man at the time of marriage. In all these cases the marriage is valid until avoided, and in the last three petition must be made within a year of marriage.

MEDICINE IN THE ROUGH

Dr. Edwin Seaborn has produced an unusual volume of medical history.[1] It is an epic of the adventures and untold difficulties of the pioneer surgeons of the prairies, and it tells of traders and log cabins, of medicine chests, wagons, and canoes, of sorties and ambushes, of buffaloes trapped in the snowdrifts, and of amputations rudely performed with the huntsman's knife. We read of François Guitault, Cartier's own physician on the voyage of 1534, who saw the Indians prescribe, for the treatment of scurvy, a broth of the green tips of spruce; of André Arnoux, who dressed the wounds of Monctalm after the battle on the plains of Abraham in 1759; of Sieur de la Salle, whose romantic travels ended, after rebuilding the fort at Starved Rock, in the naming of the State of Louisiana for his monarch Louis XIV; of René Goupil, surgeon of Anjou, and later donné in the Jesuit Mission at Quebec, who, after being cruelly tortured by the notorious Iroquois, was treacherously slain with a tomahawk in the Huron territory; and of Etienne Bouchard, of Montreal, who in 1654 perfected for his patients a comprehensive insurance scheme against all illness other than plague, smallpox, leprosy, epilepsy, and stone requiring the knife.

Indians abandoned themselves to unmitigated sorrow and ceremonial dancing when the smallpox was rife, for death they expected daily. Wolf Chief, the Brave, cocked his gun as naked he advanced on the fort, swearing vengeance on the pale-faces whom he blamed for the fatal disease; and the pipe remained unsmoked so long as the daily toll of victims grew. The practice of inoculation seems to have been known to the Red Indians, but Dr. Seaborn is surely in error when he asserts that George Christian Anthon was a protagonist of vaccination before Jenner; for the account he gives earlier of the practice of vaccination, is that of inoculation. The backwoods of medicine in the raw are shown up in the story of the theft of the solitary iron bedstead from the Port Stanley Cholera Hospital, of the futility of the hospital at Turkey Point which cost £53 but was never used, and of the objectionable practice of salting up for future dissection the unhappy victims of the gibbet.

We like the illustrations of Patrick Donnelly with his Schubert-like face, of Henry Saunders with his speedy penny-farthing, and of George H. Wilson who dressed like a cossack. We are taken also with the pictures of the early medical schools and of Dr. Joseph Lancaster's unique octagonal house. Dr. Seaborn's careful research into the history of Canadian medicine will rank as a classic of its kind, and the reader will pay his tribute to those who practised their art and profession and gave of their best on the lonely trails of the West.

DOCTORS TO BELONG TO TRADE-UNION?

At a recent meeting of the Salford city council a resolution was passed recommending the council to direct that all its employees "shall be members of their appropriate trade-unions or organisations." A suggestion in the lay press that the British Medical Association would not be recognised as a suitable organisation has been denied by the promoters of the resolution, who have also stated that the resolution was intended to refer primarily to non-union manual workers, and that if it was applied to doctors and nurses they would be free to join any association they choose. We understand that in fact the doctors and nurses working for the council have not so far been asked to comply with the resolution. Dr. J. L. Burn, the medical officer of health, has informed his colleagues that he would strongly resist any suggestion of pressure on the medical staff to join a trade-union or any particular organisation.

A resolution in similar terms is, we are informed, being considered by other local authorities.

Mr. A. Tudor Edwards, surgeon to the Brompton Hospital and surgeon in charge of the department of thoracic surgery at the London Hospital, died at St. Enodoc, Cornwall, on August 25. He was 56 years of age.

Dr. Earl Carlson, of New York, will deliver a lecture on Cerebral Palsy in Children at 4 P.M. on Monday, Sept. 9, at the London School of Hygiene, Keppel Street, W.C.1.

The Croix de Chevalier of the Legion of Honour and the Croix de Guerre avec palme have been conferred on Mr. Rowley Bristow.

LATE MAJOR R.A.M.C., MEDICAL SPECIALIST

NON-SUPPURATIVE thrombophlebitis may be primary secondary. Secondary thrombophlebitis may be the ult of trauma, local infection, general debilitating eases, or fevers, such as typhoid, pneumonia, and luenza, or may follow operation or childbirth.

Primary thrombophlebitis, or thrombophlebitis grans, is relatively uncommon. Its cause is unknown, hough Boyd (1938) regards it as a type of thrombogiitis obliterans involving only the veins. Widely parate regions of the body are affected. There is no ation to pre-existing disease or trauma of the vessels. lmonary embolism often occurs, and complete recovery usual (Swirsky and Cassano 1943). Gelfand (1943) scribes a condition of thick leg among Africans of uthern Rhodesia, the result of previous attacks of rombophlebitis of the femoral vein, which he states is t uncommon.

A syndrome of recurrent thrombophlebitis accomnied by pyrexia, often relapsing and sometimes sociated with stiff neck, occurred among askaris of the ast Africa Command during 1944.

No previous record of such a condition has been und. The outstanding nature of the disease is indicated the fact that the same clinical features have been dependently noted by several other medical officers: ajors Campbell and Wright, and Captains L. E. urkeman, A. W. Pringle, S. M. Pruss, G. M. T. Tate, . Slade, J. C. Enterican, and E. Taube.

EPIDEMIOLOGY

Occasional sporadic cases of thrombophlebitis, involvg one or more limbs, were observed in the command uring 1941 and 1942. In 1943 several patients were dmitted to hospital with œdema of unknown origin, robably the result of phlebitis, but it was not until anuary, 1944, that the disease began to assume epidemic roportions.

The syndrome first appeared in a localised area of the ommand among patients who had recently received reatment at a special treatment centre for venereal isease at Thika, near Nairobi. In April, 1944, cases of yrexia with stiff neck were described by Captain A. W. ringle at Au Barre, in British Somaliland; in August ie disease broke out among patients who had been reated at another special treatment centre for venereal iseases, this time at Mandera, British Somaliland, some 500 miles away from Thika. The outbreak reached its eak during the third quarter of 1944 and then rapidly echned. By the end of 1945 most of the recorded cases ere relapses.

The cases admitted to No. 1 (E.A.) General Hospital ud No. 3 (E.A.) General Hospital were as follows:

Quarter	*No. of cases*	*Quarter*	*No. of cases*
Jan.–March, 1944 ..	34	Jan.–March, 1945 ..	69
April–June, 1944 ..	81	April–June, 1945 ..	40
July–Sept., 1944 ..	204	July–Sept., 1945 ..	19
Oct.–Dec , 1944 ..	175	Oct.–Dec., 1945 ..	5
			627

hese two hospitals eventually received all the cases curring in Thika district. No accurate figures are tainable for the region of Mandera, British Somaliland, it the peak figures coincided with those in Kenya.

VARIETIES

The following account is drawn from the clinical features of 145 cases among East African soldiers resident in British Somaliland and Kenya during the period January, 1944–June, 1945. Three varieties of the syndrome were seen: (1) short-term fever with stiff neck often followed by relapses; (2) thrombophlebitis affecting one or more limbs, with a tendency to relapse; and (3) pyrexia, usually relapsing, without evident phlebitis. The same patient might show one or more of these varieties during the course of his disease. Thus a bout of pyrexia with stiff neck might be followed by an attack of thrombophlebitis, which in its turn might be succeeded by pyrexia without evident phlebitis.

History of the Disease.—The vast majority of the patients gave a history of having received treatment in one or other of the two special treatment centres for venereal diseases in the command. Of 83 cases in British Somaliland 58 had been admitted for syphilis and 4 for gonorrhœa. The remaining 21 cases gave no history of venereal disease and had not been resident in a special treatment centre.

History of Previous Injections.—Most of the patients had received a previous venepuncture for neoarsphenamine therapy, artificial pyrotherapy with typhoid-paratyphoid vaccine (T.A.B.), or diagnostic purposes. Of 143 cases questioned, 111 had been injected with neoarsphenamine intravenously and bismuth intramuscularly, and 9 had received either intravenous T.A.B. with intramuscular sulphapyridine or a diagnostic venepuncture. The remaining 23 gave no history of injection. The interval between the last injection and the onset of symptoms varied from three days to seven months. Of 100 cases receiving neoarsphenamine therapy, 79 developed symptoms within six weeks of the last injection. The total dosage of arsenicals administered varied from 1·65 to 6·6 g., the average being 4·4 g.

SHORT-TERM FEVER WITH STIFF NECK

This form developed either as the first phase of the syndrome or as a sequel to previous attacks of phlebitis. The onset was abrupt, though there was usually no rigor. Severe pain in the neck came on with the general symptoms of fever. On examination the patient had a raised temperature with stiffness of the neck (but no head-retraction) and tenderness of one or more muscles, most commonly the sternomastoid or the trapezius. If only one side was affected, torticollis was a common sign.

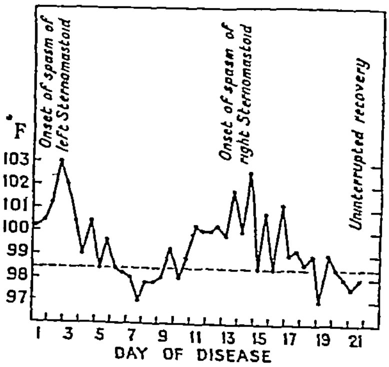

Fig. 1—Short-term fever with stiff neck, followed by stiff neck involving a different muscle.

The duration of pyrexia varied from two to thirty days, the usual course being about four days, and the temperature falling by lysis (fig. 1). The fever was commonly relapsing, the relapse being accompanied either by another bout of stiff neck, or by an attack of thrombophlebitis, or occasionally without either. Of 62 cases of short-term fever with muscle stiffness, the sternomastoids were involved in 25, trapezius 21, infrahyoid muscles 3, posterior cervical 3, neck muscles unspecified 5, erector spinæ 4 cases, and masseters 1 case.

No significant enlargement of the cervical glands was noted; neither was any evidence of cervical thrombophlebitis detected. There was no sign of meningitis, Kernig's sign being invariably negative and cerebral irritation consistently absent.

Laboratory Investigations.

Frequent examination of *blood smears* did not show either spirochætes of relapsing fever or any other parasite.

Leucocyte counts were performed in 11 cases: the total count was below 8000 per c.mm. in all cases, and a relative lymphocytosis was found in 7 of them.

The *cerebrospinal fluid* was examined in 12 cases, in 3 of which there was a cell-count of over 8 per c.mm. (all lymphocytes), the remaining 9 showing no abnormality.

THROMBOPHLEBITIS AFFECTING ONE OR MORE LIMBS

This variety was usually acute, less commonly subacute, and occasionally assumed unusual features.

(*a*) *Acute Thrombophlebitis.*—Symptoms developed either as a sequel to an afebrile period following an attack of stiff neck, or as the first incident in the course of the disease. There was an acute onset of fever, with severe pain in one limb over the site of a vein, and examination revealed severe tenderness over the affected vessel, the limb being held in protective flexion when a popliteal or antecubital vein was affected. In the event of a superficial vein being involved—e.g., the cephalic or the internal saphenous vein—the vessel could be palpated as a thickened tender cord throughout its length, it being, not uncommonly, possible to palpate a thrombosed internal saphenous vein for the whole of its course from ankle to groin. Pitting œdema was present and was particularly severe when a deep vessel, such as the femoral vein, was attacked. After an afebrile period *a relapse of fever often occurred,* accompanied by thrombophlebitis in another limb (fig. 2), or by stiff neck, or without any localising signs. The thrombosed vein, if superficial, sometimes persisted as a thickened hard fibrosed cord for many months, and was still palpable on discharge of the patient from the Army or the hospital.

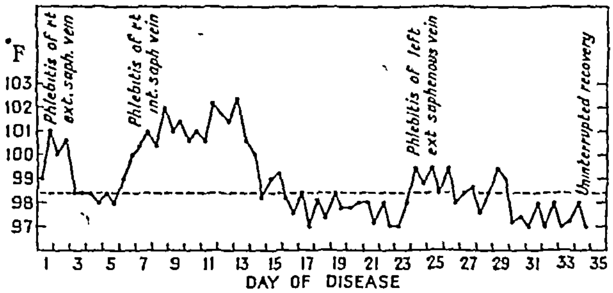

Fig. 2—Pyrexia with phlebitis, followed by two relapses with fresh phlebitis.

Special Investigations

White-cell count was performed in 26 cases. In 22 the total count was below 10,000 per c.mm., and in 4 higher. Most showed a relative lymphocytosis.

Blood-culture was performed in 6 cases, in 5 of which cultures were sterile. *B. fæcalis alkaligenes* was recovered twice from one patient's blood-culture but was almost certainly a contaminant.

Biopsy of an affected vein was carried out on 6 occasions. Some of the cases were acute and others chronic. On exposure of the affected vein under local anæsthesia it was seen to be greatly swollen, but not adherent to surrounding tissues. On section, the vein was found to be completely thrombosed in early cases; it was white and fibrous, sometimes with signs of recanalisation, in later stages. On microscopical examination no specific changes could be found. Examination of sections in acute cases revealed a simple thrombus occupying the vein, with no evidence of inflammation either of the vein wall or of the surrounding tissues. In more chronic cases organisation and recanalisation of the thrombus could be observed; one very chronic case showed *foreign-body giant-cells* in the almost completely organised thrombus. Suppuration was never observed; nor could any organisms be seen.

Culture of a vein at biopsy was performed on three occasions, a contaminant being grown in one case, the other two being sterile.

In 99 cases the following veins were involved:

One internal saphenous	15
Both saphenous	4
One femoral	22
Both femorals	21
One popliteal	21
One superficial arm vein	16
Superficial arm veins right and left	4
? Portal vein	2
	105

Of these patients 6 had phlebitis of both arm and leg.

(*b*) *Subacute Thrombophlebitis.*—Some patients were admitted with no other symptoms than œdema of one or both legs, with irregular pyrexia, pain being [illegible] absent and no thrombosed vein being palpable. The urine was free from albumin, and blood examination did not reveal anæmia. Recovery often took place without further complication, but in some cases a subsequent attack of stiff neck or of acute thrombophlebitis indicated the nature of the syndrome.

(*c*) Three *unusual varieties* may be mentioned:

(i) *Chronic.*—Two cases developed recurrent bouts of localised venous thrombosis every three weeks for five months. During each attack, which was accompanied by two or three days of pyrexia, a small tender nodule could be palpated along the course of a superficial vein. One of the patients had a typical attack of pyrexia with stiff neck, and the other developed an acute thrombophlebitis of his popliteal vein during the course of the disease. Biopsy of a nodule in each case showed an organised thrombus in a vein.

(ii) *Portal Vein Involvement* (probable).—Two patients developed ascites within a month of the termination of a course of neoarsphenamine and bismuth. Fluid thrill and shifting dullness were elicited. Œdema of the lumbar spine and legs was present in one case. There was no jaundice or albuminuria. No ova were found in stools or urine. The blood-pressure was normal. No hepatic abnormality could be discovered clinically. The ascites disappeared completely in both cases, within three months and one month. Both patients completely recovered and returned to their units fit for duty. Neither of the patients had stiff neck or thrombophlebitis of the limbs.

(iii) *Association with Arteritis.*—Two patients, admitted to hospital with phlebitis, developed thrombosis of the femoral arteries, with resultant foot gangrene. Each case required amputation of the leg above the knee, after which recovery took place.

(*d*) *Complications and Sequelæ.*—A notable feature was the complete absence of embolism. A common sequela was persistent œdema of one leg; because of this many patients had to be invalided out of the Army. No death resulted from this disease in these 145 cases.

PYREXIA, USUALLY RELAPSING, WITHOUT EVIDENT PHLEBITIS

This variety was characterised by irregular pyrexia lasting from three days to three weeks, without evident phlebitis. In some cases the pyrexia ensued as a sequel to an attack of stiff neck or phlebitis; in other cases one or other of these syndromes developed as a complication after the termination of the fever. But many cases displayed no localising signs, the diagnosis being suggested by a history of recent antisyphilitic therapy, and by the coexistence in the same area of more typical cases of the disease.

DIFFERENTIAL DIAGNOSIS

Pyrexia with Stiff Neck.—The differential diagnosis from relapsing fever, cerebrospinal meningitis, and malaria was readily settled by the repeated absence of spirochætes and malaria parasites from the blood, and by the normal cerebrospinal fluid. Acute myalgia of neck and shoulders in epidemic form has been described by Beeson and Scott (1942), and cases of persistent myalgia following *sore throat* have been recorded by hton and Jones (1942), but in neither instance ıny association with thrombophlebitis or injections ioned.

rombophlebitis.—The acute form had to be diagnosed pyomyositis, which was differentiated by the marked local swelling, the absence of signs over site of a vein, the absence of peripheral œdema, the tendency to pus formation.

bacute bilateral thrombophlebitis of the legs had distinguished from other causes of œdema, such as ritis, anæmia, cardiac failure, vitamin-B_1 or protein iency, and epidemic dropsy. The differentiation these diseases only arose in those cases where no of thrombophlebitis was evident. Examination urine, blood, and cardiovascular system readily uded renal, blood, and cardiac disease. Beriberi eliminated by the absence of neurological or of liac abnormality, and protein deficiency was excluded he normal plasma-protein level (estimations in 3 cases 8·95 mg., 8·83 mg., and 8·36 mg. per 100 c.cm.). residual swelling was distinguished from filariasis the pitting character of the œdema.

elapsing Pyrexia without Evident Phlebitis.—When ver two weeks' duration this pyrexia had to be inguished from other long-term fevers, such as hoid, kala-azar, undulant fever, and miliary tuberısis. Negative cultural and serological reactions, ative sternal puncture, and normal chest radiograms luded these diseases. The history of recent treatment special treatment centre for venereal diseases, the istence of more typical cases of the disease in the e area, and in some cases the supervention of an ck of acute phlebitis or stiff neck clinched the gnosis.

DISCUSSION

t might be thought that the description which has n given is not that of a syndrome, but of a mixture of rt-term fevers, unrelated cases of thrombophlebitis, long-term undiagnosed pyrexias. They have been cribed together as a syndrome for the following sons:

A sudden outbreak of thrombophlebitis, with subsequent decline in numbers of cases, occurred in two widely separated areas of the command. Previous cases could scarcely have been missed, as reliable observers were present before the outbreak in these areas.

Several observers, who had had no previous information on the subject, made simultaneously and independently the observation of the association of the short-term fever with stiff neck, often followed by relapses, with thrombophlebitis affecting one or more limbs, and later with the pyrexia without evident phlebitis.

The association of these three manifestations is shown below:

	Cases
hort-term fever with stiff neck alone	8
hrombophlebitis alone	23
yrexia without evident phlebitis alone	8
ıort-term fever with stiff neck and thrombophlebitis ..	13
hort-term fever with stiff neck and pyrexia without evident phlebitis	5
hrombophlebitis and pyrexia without evident phlebitis ..	3
ıort-term fever with stiff neck, thrombophlebitis, and pyrexia without evident phlebitis	7
	62

n searching for the cause of this peculiar syndrome ee possibilities were entertained: (1) that it was a us disease like infective hepatitis; (2) that it was due the local effect of neoarsphenamine or other antiıhilitic drug on the vein; and (3) that it was allied marantic thrombosis.

'irus Disease.—The points in favour of a virus origin the relative lymphocytosis, the negative bacterioical findings, and its possible ætiological and epidemioical relationship to infective hepatitis in this comnd. The admissions for infective hepatitis to two ıeral hospitals at the time of this outbreak are shown in fig. 3. The similarity between the two curves will be noted. Most of the cases of infective hepatitis were so-called postarsphenamine jaundice in patients undergoing antisyphilitic treatment. That infective hepatitis can be transmitted by syringes has strong support. Of 62 patients developing this syndrome, 5 had previously had jaundice, and 2 developed thrombophlebitis while still undergoing treatment in hospital for jaundice. The theory that the present syndrome may be caused by a virus transmitted chiefly by needle puncture, but also by other means, such as droplet, urine, or fæces, is attractive.

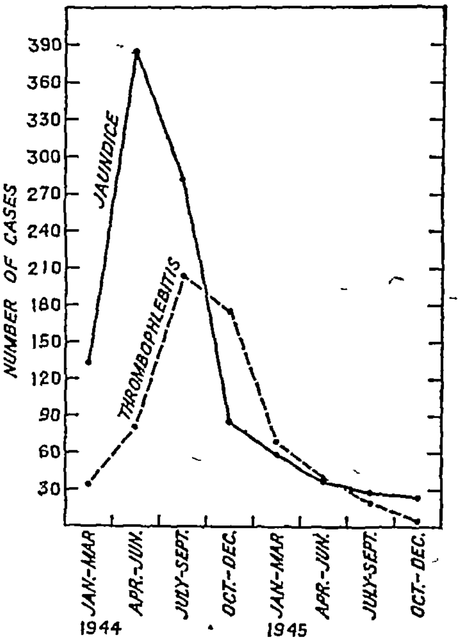

Fig. 3—Admissions to No. 1 and No. 3 (E.A.) General Hospitals of cases of jaundice and of thrombophlebitis from January, 1944, to December, 1945.

Rift Valley fever, a virus disease, is endemic in East Africa. The sera of two patients, taken in each case on the second and twenty-first days, were examined by Dr. K. C. Smithburn, of the Yellow Fever Research Institute, Entebbe, but no antibodies to the virus of Rift Valley fever were found.

Local Effect of Drugs on Veins.—The prolonged course of the pyrexia suggests that the cause of the phlebitis is an infection rather than a chemical irritation of the veins by antisyphilitic drugs. The predisposing effect of arsenic or bismuth cannot be doubted. It is possible that one or other of these drugs so damages the veins as to make them susceptible to infection. It will, however, have been noted that some of the patients had received no previous antisyphilitic therapy.

Marantic Thrombosis.—Thrombosis of limb veins occurs in severely malnourished persons, but most of these patients were healthy African soldiers of category A, who were better nourished than their civilian compatriots, among whom thrombophlebitis is unusual.

SUMMARY

A syndrome occurring in East African soldiers is described. The main features were pyrexia associated with stiff neck or thrombophlebitis, and usually accompanied by relative lymphocytosis. There is a great tendency to relapse.

The association with antisyphilitic treatment is emphasised.

The possible causes are discussed.

We are grateful to Brigadier R. P. Cormack, O.B.E., director of medical services, East Africa Command, for permission to publish this article, and to Major J. E. McClemont, R.A.M.C., for some of the pathological investigations.

NAUSEA AND VOMITING OF PREGNANCY

A STUDY IN PSYCHOSOMATIC AND SOCIAL MEDICINE

G. GLADSTONE ROBERTSON
M.D. Glasg.

MY interest in the nausea and vomiting of pregnancy originated in some observations I made, in general practice, on dyspepsia in non-pregnant women. I had noted that a particular dyspeptic syndrome, usually attributed by its sufferers to "a weak stomach," was not uncommon in married women who were sexually frigid. A short account of this syndrome is as follows.

The symptoms usually began soon after marriage, or, if later, with the cessation of sexual interest. In its initial phases the syndrome usually appeared at times of the day which could be related to the impending threat of coitus—i.e., in the late evening—or at the week-end.

The earliest and most constant symptoms were abdominal distension, eructation of wind and of small quantities of gastric juice (usually termed "acidity"), and an increasing distaste for fats, with a decreased ability to digest them. Attacks of nausea appeared later, with or without vomiting, which was often described as "biliousness." Pain was present only in long-standing and severe cases, in which discomfort was almost constantly present. The condition was liable to persist indefinitely but with little or no deterioration in general health.

Some of the patients were known to me before marriage, when there was nothing to indicate that they were abnormal. As a whole they did not lean towards any personality group—e.g., hysterical or obsessional—or towards any special psychiatrical category, such as anxiety state. On the other hand, if the illness had lasted for years, it was the exception to find a patient who did not exhibit signs of anxiety.

A study of the emotional state of these patients at the time of the onset of symptoms revealed a common feature—i.e., sexual relationship with the husband gave rise to disgust. The digestive disorder appeared to be a physiological response to the repetitive effect of this emotion. Further, most of the patients came to dread coitus and to develop signs of anxiety. The subsequent nervous element was as clearly a response to fear as the digestive disorder was to disgust. Neither disorder was causally related to a primary psychoneurosis.

When I first recognised this syndrome in 1938 I named it "rejection dyspepsia" (unpublished). During the succeeding years I have confirmed the findings in many hundreds of women. In doing so I noted that a high proportion of them at marriage were unduly attached to their mothers. The syndrome is common and includes, almost without exception, married women labelled as having visceroptosis and the great majority diagnosed as cases of nervous dyspepsia. Towards the end of 1943 I became impressed with the observation that women with this syndrome invariably had a history of protracted or severe nausea and vomiting during their pregnancies.

These and other observations suggested the possibility that the nausea and vomiting of pregnancy might also be related to frigidity. Accordingly I began to investigate my pregnant patients and the histories of their past pregnancies from this point of view. It appeared that frigidity in the strict sense—i.e., the experiencing of coitus as an act undesired in itself and unaccompanied by the attainment of orgasm—did not inevitably cause nausea and vomiting during pregnancy; but severe or long-continued vomiting in a frigid woman during pregnancy was related directly to the frequency of undesired and unappreciated coitus. A further characteristic associated with nausea and vomiting was that the woman was excessively attached to or dependent on her mother. This personality trait appeared to be relevant to nausea and vomiting even when the sexual functioning of the woman was "normal." Another characteristic which seemed to be ætiologically associated was a history of previous dyspepsia.

Serial Investigation of Pregnant Women

To evaluate the relevance of previous dyspe excessive attachment to the mother, and distr sexual functioning in the ætiology of the nausea vomiting of pregnancy, I investigated 100 consec pregnant women. The results are analysed in tal which shows that 57 had nausea or vomiting and 43 none. The latter group can therefore be regarde controls. The table shows that 6 out of 57 cases h history of previous dyspepsia, against none of controls; 20 out of 57 cases showed undue mother at ment, against 4 out of 43 controls; and 40 out of cases showed disturbed sexual functioning, aga 4 out of 43 controls.

These findings confirmed that a history of previ dyspepsia, mother attachment, and disturbed se functioning were ætiologically significant in the nausea and vomiting of pregnancy.

TABLE I—DETAILED ANALYSIS OF CONTROLS AND CAS

—	Cases	Previous dyspepsia	Mother attachment			Disturbed sexual functioning		
			1	*2*	Total	*1*	*2*	
Controls ..	43	0	4	0	4	4	0	4
Nausea and vomiting:								
Minor ..	31	5	6	0	6	14	4	18
Moderate ..	17	1	5	3	8	6	7	13
Severe ..	9	0	3	3	6	0	9	9

DEFINITION OF TERMS AND STANDARDS OF ASSESSMENT

Previous Dyspepsia.—This term refers to those patien who had had recurrent attacks of dyspepsia for se years *before marriage.* These comprise 6 cases only a number too small for further subdivision. The di order in 3 of these was said to have dated from "acidosis in childhood. All 6 had nausea and vomiting in preg nancy.

Mother Attachment.—The trend of development in th growing girl is towards an increasing freedom from th earlier dependence on the mother. On marriage, mo especially when she herself becomes a mother, a wom should be able to behave as an independent adult mothe In some women, however, the infantile and childi relationship with the mother persists, and they remai enclosed within the orbit of the mother's influence injunctions, and prohibitions. In other women th extreme devotion expressed for the mother is (to th appreciative observer) seen to be a compensation fo repressed aggressive tendencies directed against he Such tendencies are often found in a woman who is forced by circumstances to care for an invalid mother be attending to her own household duties during the ea years of marriage. If the young married woman to live with her mother or a mother substitute—e mother-in-law—the conflict between outward d (devotion) and inward resentment (hate) is exaggerat as a result of propinquity.

Mother attachment varies from woman to woma varies in its predisposing conditions, and varies in th same woman at different times. Its importance in th nausea and vomiting of pregnancy is usually greater during the earlier pregnancies. With the passage o years it tends to wear off and its ætiological influence tends to decrease.

For the purpose of this inquiry I have used the numerals 1 and 2 to indicate the degrees of undue mother attach- ment estimated to prevail at and immediately befo onset of the pregnancies studied. Thus, if after arriv the woman continues to visit her mother *daily* ates her dependence on her by making no decision nportance without consulting her the degree of ıer attachment was assessed as 1. When dependence ıis sense is very pronounced, or when the patient ribed her interest in her mother as being greater her interest in her husband, the degree of mother chment was assessed as 2.

hy should undue mother attachment be the equi- nt of a disgust factor in the subconscious? A hiatrical interpretation might infer that the first essive feelings of the baby are directed towards the her and are associated with anal activity. When ater life, as a result of cultural influences, bodily etions become linked to dirtiness and filth, any ressive feeling towards the mother becomes like- associated with filth. The psychiatrist tells us that -devotion to the mother is a disguise or compensation aggressive tendencies.

nother and less complex explanation may be given ch has the advantage of being more easily grasped the patient. At various periods in the growth of the mal child he takes or steals what he desires, lies to ıpe punishment, and later becomes interested in his y and genital functions. These impulses are con- led and corrected chiefly by the mother, and as he uires cultural education he tends to become ashamed ıis past behaviour. This is shown by the inability he average person, of any age, to discuss without barrassment certain subjects, particularly of a sexual ure, in the mother's presence. It can even be said t for the remainder of his life the very sight of his her induces in him subconscious shame.

isturbed Sexual Functioning.—An obvious form of urbed sexual functioning is frigidity in the sense t the woman has no interest in coitus, never experi- es orgasm, and may have vaginismus. My own ervations indicate that about 10% of married women into this category of complete frigidity throughout whole of their married lives, and that many others, ecially overworked women with large families, ulti- tely reach such a state. Most women with this racteristic were noted to have undue mother attach- nt before and during the early years of marriage. seems that well-marked emotional entanglement with mother tends to inhibit the normal expression of the man's love for her husband. That the public mind ware of the discomfiture experienced by the husband ough undue interest on the part of his wife in her ther is shown by the popularity of mother-in-law es (invariably the wife's mother). Other forms of turbed sexual functioning related ætiologically to the ısea and vomiting of pregnancy are continuous loss exual interest and inability to attain orgasm. Among factors associated with and precipitating these are the part of the woman) ill-health, frequent child- ring, and fear of pregnancy.

Jnderstanding of these conditions is, however, incom- te unless account is also taken of the sexual ıctioning of the husband, which may show either xpertness or disturbance. For example, excessive tal demands made by the husband may, if long eated, induce in the woman feelings of revolt and gust, attended by loss of sexual interest. Infrequent ercourse, on the other hand, is not so likely to build a massive reaction of disgust. This is illustrated the absence of sickness in the strictly frigid married man who has intercourse on relatively infrequent asions and in the unmarried woman who has inter- ırse only once or twice in the absence of orgasm and en in the presence of painful discomfort. Continued culatio præcox in the husband during early married may also lead to the growth of disgust in connexion h coitus, because it prevents the wife from realising npleted orgasm and the sexual act becomes associated h mere messiness. The inability of the woman to ain orgasm may also be determined by the repeated ıctice of coitus interruptus.

Inquiry was also made into the proportion of coital acts undesired by the wife and the proportion of coital acts in which she did not attain orgasm during the months preceding conception. Sexual functioning was regarded as reasonably normal when the proportion of undesired coitus and absence of orgasm did not exceed 20%. When either proportion exceeded 20% but was less than 60%, the disturbance of sexual functioning was assessed as 1; when the proportion exceeded 60%, the disturbance was assessed as 2.

Coital Infrequency.—As the theme of this discourse implies that pregnancy sickness is caused by a massive "disgust" factor in the subconscious, some method had to be devised to exclude from the disturbed sexual functioning category those patients who had experienced coitus on relatively infrequent occasions. Accordingly, no patient was included in this category in table I if coitus took place less frequently than once a month or six times in all.

Thus, disturbed sexual functioning was not taken into account in 6 controls, although all were frigid in the sense of the definition given above: 2 were unmarried and had experienced coitus on three and four occasions; 2 had married soldiers towards the expiry of embarkation leave; and 2 had been married for some years but asserted definitely that coitus had not taken place oftener than eight or nine times a year.

Though undesired coitus during pregnancy might well have a bearing on the severity of sickness, it was found expedient to limit the inquiry to a period of a few months before the beginning of pregnancy. Many of the women had not experienced coitus during pregnancy, notably the wives of men serving with H.M. Forces.

Degree of Nausea and Vomiting.—The cases were divided into three groups: minor, moderate, and severe. In the minor group nausea, retching, or vomiting lasted less than six weeks; in the severe group those symptoms were prolonged beyond five months, or, if of shorter duration, were of such severity as to be classified as true hyperemesis gravidarum—i.e., the fluid output exceeded fluid intake. The moderate group lay between the minor and severe groups.

DETAILED ANALYSIS

Detailed analysis of controls and cases is given in table I which shows that minor cases (31) were almost twice as common as moderate cases (17), and these in turn almost twice as common as severe cases (9). This table also indicates clearly that the ætiological significance of mother attachment and disturbed sexual functioning is higher in severe than in moderate cases; higher in these than in minor cases, and higher in minor cases than in controls. Thus the percentage with mother attachment in controls was 9; in minor cases 19; in moderate cases 47; and in severe cases 66. The percentage with disturbed sexual functioning in controls was 9; in minor cases 58; in moderate cases 76; and in severe cases 100. The greater significance of both mother attachment and disturbed sexual functioning in severe than in minor cases is also indicated by the progressive percentage increase in degree-2 cases compared to degree-1 cases as we pass from the minor through the moderate to the severe group.

Variations of Nausea and Vomiting in Successive Pregnancies in the same Woman.—The series of 100 pregnant women comprised both primiparæ and multiparæ. The multiparæ numbered 63 and between them gave a history of 175 previous pregnancies. The syndrome of nausea and vomiting was not necessarily a constant feature for successive pregnancies in the same woman. Some of the controls in this series were "cases" in their previous pregnancies, and vice versa. The presence or absence of vomiting in any single sequence of pregnancies in the same woman could usually be related to the life situation prevailing before conception—e.g., the relationship to the mother, the attitude towards the husband as a person, and the behaviour of the husband as a lover. An analysis of the 175 previous pregnancies gave results which corresponded to those obtained in the present series of 100 pregnancies.

Table II shows, in six illustrative cases, the sickness variability in a succession of pregnancies in the same woman and the significance of previous dyspepsia, mother attachment, disturbed sexual functioning, and coital infrequence. Though these cases were selected they are typical of the entire series comprising 275 pregnancies.

CASE 1.—A sequence of five pregnancies free from nausea or vomiting in the absence of the factors previous dyspepsia, mother attachment, and disturbed sexual functioning. She desired the first, was resigned to the following three, and averse to the last. In no patient does conscious attitude to pregnancy bear any relationship to sickness.

CASE 2.—Occasional attacks of biliousness dating from school days. When previous dyspepsia is the only factor, the degree of sickness is usually constant in all pregnancies in the same woman.

CASE 3.—Devoted to and nursed mother with pernicious anæmia. Mother died shortly after pregnancy 5. Disturbed sexual functioning throughout the years of marriage was 25%.

CASE 4.—Lived next door to and assisted her mother, to whom she was much attached until after pregnancy 3. On removing to another district she became detached from her mother. After pregnancy 4 her sex interest began to wane. After pregnancy 5 she became completely frigid.

CASE 5.—This woman was completely frigid. Her husband, like many married to such women, became a drunkard and later unfaithful. He contracted syphilis after pregnancy and they separated. Before conceptions 8, 9, 10, and 11 broke into the house (on the evidence of a neighbour and her own testimony) and intercourse took place on only occasion before each pregnancy.

TABLE II—SICKNESS VARIABILITY IN SUCCESSIVE PREGNANCIES IN 6 TYPICAL CASES, SHOWING SIGNIFICANCE OF PERSONALITY FACTORS

Case	Pregnancy	Age (year)	CAP	PD	MA	DSF	CI	Total points	Nausea and vomiting
1	1	20	D	0	0	0	—	0	0
	2	21	R	0	0	0	—	0	0

	9	40	A	0	0	2	+	0	0
	10	43	A	0	0	2	+	0	0
	11	44	A	0	0	2	+	0	0
6	1	31	D	0	2	2	—	4	3
	2	34	D	0	2	2	—	4	3
	3	36	D	0	2	2	—	4	3

The last pregnancy in each patient was one of the 100 consecutive pregnancies.

CAP, conscious attitude to pregnancy: D, desire for the pregnancy; R, resigned to being pregnant; A, averse *to the pregnancy*.

PD, previous dyspepsia.

MA, mother attachment.

DSF, disturbed sexual functioning.

CI, coital infrequency. A plus sign indicates the presence of this factor, when the DSF factor loses significance as an agent capable of causing sickness.

Total points are obtained by adding together degrees of PD, MA, and DSF. (DSF points not included if CI present.)

Degree of nausea and vomiting: minor 1, moderate 2, severe 3.

CASE 6.—She illustrates the effect of a combination of t factors mother attachment (to a marked degree) and comp frigidity. All pregnancies were complicated by hyperem gravidarum. The first two terminated in stillbirth at 29th and 31st week respectively. The third continued *the 35th week with survival of the child.*

Vomiting and Miscarriage in the Wives of Ex Service Men.—Although as has been indicated nausea and vomiting of pregnancy may be ætiologi complex, the practical considerations become narro down when a previous pregnancy was free from sickn During recent months, in the course of general practi I have encountered an unusually high proportion of m carriages preceded by severe vomiting among the of ex-Service men who had been absent for two or m years. Many of the wives had undergone one or m previous pregnancies without sickness. In such cas one would expect, in view of the findings recorded in th paper, that frequent undesired coitus had before the recent pregnancy; inquiry showed that was so.

Many men, returning home after an absence of years seem to be unaware that their wives have adjusted themselves to a different mode of life and may in fac have ceased to be in love with them in the physical sense The vigour, physical fitness, and sexual hunger of the men contrasts with the war-worn condition of th harassed housewife. If regular coitus is not preceded by a preliminary courtship there is grave danger not only of severe vomiting during an ensuing pregnancy, wi an apparent increased risk of miscarriage, but also alienation of the affection of the wife.

These and similar aspects of human contact a relationship, with their unlimited potential for unhapp ness and ill-health are the true kernel of Social Medicine The inception of university chairs of social medicine le one to believe that an endeavour was about to be ma to equip the doctor of the future to grapple with su problems, but apparently the subjects for research to be well-worn topics like vital statistics, drainage, a impurities in food and milk.

ADDITIONAL FINDINGS

The compilation of this series of patients began o April 1, 1944, and was complete in ten weeks. Wi the exception of three women who miscarried on th occasion of the first attendance, every pregnant wom treated in the course of practice was included in th series. Whether the pregnancy was at an early or at late stage during this period, recorded data were ava able from the first examination, and the inquiry was finally concluded until after the delivery of the patient.

The blood-pressure curve tended to rise more in patients who suffered from severe and protract vomiting.

Four patients had pyelitis during some stage of th pregnancy, and 2 had albuminuria. All 6 had nau and vomiting. In all these cases nausea and vomiting pre ceded the rise in blood-pressure, pyelitis, or albuminu

Most textbooks comment on the higher incidence of pregnancy sickness among "nervous" or "neurotic women. Most of the 100 patients were known to re during previous pregnancies and often before marria Nervous or neurotic trends were apparent in some bef marriage, but in others not until some time after marriage. The impression gathered was that the incidence of sick ness was definitely higher in the latter group. finding is consistent with the view that the sickness o pregnancy is not due to "nervousness."

Ætiology

he ætiology of the nausea and vomiting of pregnancy received considerable attention, but no definite nclusion has been reached. An excellent review of the ject was provided by Hall (1943). No toxin has n discovered. Willis et al. (1942) and Weinstein al. (1943) consider deficiency of components of the amin-B complex, notably vitamin B_6, to be a factor importance, whereas Kemp (1933), Bandstrup (1939), d Kotz and Kaufman (1940) emphasise abnormal anges in the maternal adrenal cortex. Shute (1941) d Schoeneck (1942) observed changes in the quantity gonadotropic hormone in the urine and blood of tients suffering from nausea and vomiting. No ecific pathological lesion has been noted, and the st-mortem findings (associated with hyperemesis avidarum) are consistent with what might be expected the end-result of protracted vomiting and lack of food d fluid (Sheehan 1939). Psychological factors have also en considered, and Weiss and English (1943) express e following view:

> “ A conscious or unconscious wish not to become egnant: if the unconscious aversion is masked by a nscious desire to become pregnant, sickness is likely be severe: an unconscious belief that a sin has been mmitted: childhood fantasies suggest that the preg- ncy has taken place by way of the gastro-intestinal act and the unconscious desire to be rid of the fœtus nceives its expulsion in the same way.”

This opinion, however, was not borne out by statistical alysis of the conscious wish to be pregnant or not egnant in my series of 100 patients; nor does it explain e sickness variation in a sequence of pregnancies in e same woman. It savours more of armchair deduction the abstract than of clinical observation (see table II). A discussion of the ætiology of the nausea and vomiting pregnancy may most conveniently be arranged in rms of Halliday's (1943) formulation of ætiological inciples.

ÆTIOLOGY OF ONSET

The Person.—What kind of woman on becoming egnant develops nausea and vomiting? Relevant rsonality characteristics are disturbed coital function- g (acquired in adult life, often short-acting, may vary om pregnancy to pregnancy); undue mother attach- ent (usually acquired in adolescence, tends to decrease); d, less often, previous dyspepsia (usually dates from ildhood and remains fixed).

Environment.—Why does a pregnant woman develop omiting when she does? Among relevant environmental ctors are the physical propinquity of the mother and sband, the husband's behaviour as a lover, and the equency of his coital demands.

Mechanism.—Why does a pregnant woman's ailment ke the form of nausea and vomiting? A psycho- matic approach suggests that the nausea and vomiting ay represent the physical expression of an emotional nstellation in which disgust is predominant. It also ggests that the biochemical changes associated with egnancy probably lower the threshold of the physical pression of a latent or subconscious disgust; hence, hen the ovum dies or the fœtus is removed, the thres- old to physical expression is again raised and vomiting ases. In other words, pregnancy serves as a trigger. hese suggestions are consistent with the absence of y proved toxin, the probable change of hormonal cretions accompanying subconscious emotional activity s well as pregnancy), and the absence of any specific thological lesion.

ÆTIOLOGY OF NATURAL RECOVERY

Why does the patient recover without treatment? omen with nausea and vomiting of pregnancy may cover spontaneously in a few weeks when the illness is mild. In more severe cases removal from the proximity of the mother or the husband is often followed by rapid improvement. A study of successive pregnancies in the same woman shows how the presence or absence of vomiting in the various pregnancies is usually governed by the presence or absence of the operative environmental factors already described.

ÆTIOLOGICAL PRINCIPLE OF THE PREVALENCE

The theory that nausea and vomiting is an expression of the emotional life, especially of a heightened sense of disgust, covers the known facts in terms of person and environment (biological ætiology), the known facts in terms of the bodily organs and functions involved (ætiology of mechanism), and the known facts of the ætiology of natural recovery. Further, it can be shown that it does not conflict with the principle of “prevalence,” which is that if the incidence of a disease does not conform with what we have inferred concerning its ætiology, then our inferences are faulty, partial, or erroneous (Halliday 1943).

The published work shows that the incidence of the syndrome is not primarily related to physical factors of environment, such as climate or diet, but is clearly associated with the psychosocial set-up sometimes called western civilisation. Thus the incidence is low among Eskimos and native African tribes (Dieckmann 1938). In oriental countries, except industrialised Japan (Hall 1943), hyperemesis gravidarum is practically unknown. It is common in modern capitalist industrial countries, such as western Europe and America, and is more prevalent in urban than in rural areas. Dieckmann, investigating the incidence of hyperemesis in various climates, also notes that it was relatively rare in Germany during the war of 1914–18, but that a well-marked increase took place in the following years. The ætiology of this change in prevalence is complex, but it could be attributed to the different psychosocial environment prevailing in the war years contrasted with the post-war years, notably the separation of husband and wife during the years of combat (see above).

A further interesting fact, remarked on by veterinary surgeons and farmers, is the absence of vomiting in pregnant animals. Though the physical accompaniments of pregnancy in many animals closely parallel those in woman, the female animal is free from a sense of shame in the presence of the mother, nor does she submit to coitus from a sense of duty to the male.

Therapeutic Inferences

As in most illnesses, ætiological insight emphasises the importance of prevention rather than cure—e.g., the need for more knowledgeable upbringing of the young, reasons why a woman should marry in accordance with her instincts rather than to attain social position, and the necessity for marital education in the newly married. Nevertheless the results of this inquiry into ætiology have definite therapeutic implications. Knowledge of the ætiological importance of mother attachment, disturbed coital functioning, and the frequency of undesired coitus enables the doctor to focus his inquiries on those characteristics of the patient's personality and her life situation which are of ætiological relevance. Patients with severe nausea and vomiting in pregnancy have usually endured a good deal of mental anguish, and, because of the delicacy of the problems involved, rarely make confidants spontaneously. There are few of them who cannot be materially helped by bringing to light their particular difficulties.

When a history of previous dyspepsia was the only factor present, the degree of sickness was usually a constant in all pregnancies in the same woman. Though it might persist for a few months, it was rarely severe. On only two occasions, where the onset was traced to events at the unusually late age of between 12 and 14 years, was I able to discover significant factors or to influence the normal course of the illness. Where a strong mother tie exists, this can easily be discussed freely, provided a reasonable amount of tact is used. Most women are not upset to learn that it is neither virtuous nor wise to be bound indefinitely by their mother's apron-strings. Where previous undesired coitus is realised to be a factor, this can be discussed with both husband and wife, He is inevitably unaware of the possible significance this may have in relation to the sickness of his wife.

Although many of these talks were instigated by me in pursuance of an idea and to obtain statistical data, the underlying and inspiring purpose was to bring about cessation of sickness, and, through change of habit in the life situation, to prevent sickness in future pregnancies. Each patient should be studied as an individual. Treatment in any particular case depends on the particular findings. The approach must be sympathetic, tactful, unrushed, and in privacy. If success is to be achieved, the patient, besides replying to question and unburdening herself of her affairs, should receive an acceptable explanation capable of convincing her that the factors discovered by inquiry were really the cause of her vomiting. The second interpretation given above on the significance of mother attachment as a sickness-producing factor is much more readily understood than the first. In my experience no woman, however dull, has the slightest difficulty in believing that the effect of frequent undesired intercourse is cumulative in the subconscious and leads to a personality change which manifests itself as an increased tendency to vomit. It may be necessary to remove the patient from the propinquity of the mother or husband. She may be benefited by the knowledge that the question is being taken up with her husband. As a general rule several factors—e.g., mother attachment and frigidity—are found in the more severe cases of vomiting.

After such discussions the improvement is often dramatic, especially among recently married women. An older woman, however, who has been frigid from the beginning—e.g., a multipara, perhaps pregnant for the twelfth time—may present more difficulty. In such a woman the disgust may be so chronic and deep-seated that it finds physical expression even between her pregnancies in the syndrome of "rejection dyspepsia," as already described.

It is not easy to detail statistically the results of treatment in a condition so variable as the sickness of pregnancy; hence only 4 of the more severe cases will be considered, 3 of them briefly. All 4 women were completely frigid—i.e., at no time in their lives had there been sex interest—and all showed also mother attachment: 3 of them of the second degree and 1 of the first degree. When first attended 2 of the patients, besides being violently sick, were bleeding slightly from the uterus and having mild pains. Both were between seven and nine weeks' pregnant, both improved much in two days, and both stopped vomiting within two weeks. One remained well, but the second, who was living with her mother, had two severe recurrences, one accompanied by an attack of pyelitis, in the later months of pregnancy. Each recurrence had followed a domestic crisis which required further investigation and treatment. The third (table II, case 6) continued to have nausea and vomiting until she entered labour at the 35th week. Although vomiting appeared to diminish in intensity, treatment was less successful than in any other case in the series, and she was the only patient in whom pregnancy did not reach full term. The fourth patient, aged 27, in her second pregnancy (one of the 2 cases of albuminuria), is described in greater detail.

Her mother approached me through a neighbour whom I had treated during pregnancy. The patient was in hospital with the diagnosis of toxæmia of pregnancy. Next day she was conveyed home by ambulance against stern advice. She was visited once only. Half an hour was occupied in obtaining the following story and in making the psychopathological interpretations and suggestions thought necessary.

Life Situation and Emotions.—Her husband served in the merchant navy. The marriage took place during a period of leave, eighteen months previously. Conception took place during his fourth spell ashore. She was devoted to and dependent on her mother, with whom she lived when her husband was at sea and whom she visited, forenoon and evening, during his periods of leave. She said she was very fond of her husband but felt revolted and disgusted when physical relationship took place, which was frequently when he was at home. Each time he left her to resume his hazardous duty she was filled with remorse and guilt because she had so little of herself to give him and a sensation of terror lest, as a result of a torpedo, she might never have another chance of seeing him. About two weeks after conception and before she was aware of pregnancy, her doctor advised a rest from her work in a munitions factory and certified her as unfit owing to hyperthyroidism. Two weeks later vomiting began. When three months' pregnant, she was admitted to the maternity hospital, in which she was detained for four months. During this period there was daily vomiting, intermittent albuminuria, and a moderate rise in blood-pressure.

Progress.—After a discussion of the relevant problems, vomiting ceased in 24 hours. Appetite returned. She was out of bed in a few days, and out of doors a week later. When the hospital almoner called at the end of the second week she was out shopping, having gained a stone in weight. When the patient called at my consulting-rooms three weeks after her homecoming, her urine was free from albumin and her blood-pressure was 125/80, at which level it remained until her uneventful delivery.

"Psychosomatic" and "Psychoneurotic"

The psychosomatic concept has been the subject of much confused thinking, and perhaps in no field of medicine is there a greater need for the "integration of medicine," advocated with enviable artistry by Walshe (1945). The psyche-soma interrelationship has been influenced by Freudian beliefs and analogy, and indeed many writers apply the same principles to "psychogenic" somatic disorders as were found useful in the study of psychoneurosis. Briefly, these principles suppose that it is determined either genetically or in babyhood or in childhood *how* the patient will break down in health, should his later life stresses be too great. Adult difficulties are lumped together as "anxiety" and are regarded merely as the factors which precipitate the breakdown in point of time. In other words, whether the stress is caused by flying a bomber over enemy territory or by marrying a frigid wife, the form taken by the resulting illness will be the same unless experiences before or shortly after birth determined otherwise. Others again still speak of an illness as being either physical or psychogenic. For them "psychosomatic" is a euphemism for psychoneurotic. Thus, though they have come to use new words, they continue to think in terms of the outmoded classification of functional or organic.

Such views are alien to those expressed in this paper which postulate a psychosomatic disease or disorder to be a specific physiological response to a particular type of emotion capable of being incorporated into the personality at any age. The persistence of the disorder is determined by the intensity and frequency of the causal emotion and the age when it is experienced. For example:

(1) *Coronary thrombosis* has been called by some the doctors' disease. The high incidence of this disorder among doctors is surely not because they are the subject of any special hereditary traits, or suffered from particular psychological traumata in childhood, or because they feed on an imperfect diet or live in damp houses, or because their physical or even intellectual output is unduly high, but rather because of the emotional accompaniments

their duties—factors such as hurry and tension, undue sponsibility, and fear of a diagnostic error or unkindly dgment, with possible repercussions on their means livelihood.

(2) *Enlarged Prostate.*—The prostate is normally tivated by erotic emotions mediated by endocrine, otably gonadal, activity. Few would deny that some rm of over- or mal-activity is responsible for the timate enlargement, a view supported by the freedom the eunuch from both the predominant emotion and ormone and from enlarged prostate.

These two diseases, unquestionably physical, and sulting from the repetitive effect of specific emotional onstellations in adult life, appear to fall into the psycho-omatic category. Neither need be associated with sychoneurosis.

It is certain that "disgust-shame" factors may find heir way into the subconscious through life experiences ther than those expressed by the conceptions "previous yspepsia," "mother attachment," and "disturbed exual functioning." For instance, it is probable that woman who was an inhabitant of a besieged city and as so unfortunate as to be reduced to a diet of cats, ats, and mice, would suffer from vomiting if she became egnant soon afterwards. On the other hand, there as no evidence of a rise in either the prevalence or the verity of the nausea and vomiting of pregnancy mong the blitzed citizens of London and such intensely ombed areas, although there was an increase in the ncidence of psychoneurosis. Some of the most highly eurotic women in the series were free from nausea and omiting, in the absence of the described causal factors. The sickness of pregnancy can be defined as a psycho-omatic reaction. This behaviour pattern is separate nd distinct from the emotional quality popularly con-eived by the expression "psychoneurotic."

From a survey of a very much larger series than the 00 women who form the basis of this paper, other factors ppeared to be ætiologically relevant in a small ercentage of cases. Thus, the syndrome developed in vomen with strong aggressive feelings towards the father; n women born in humble circumstances whose life was lominated by an attempt to compensate in appropriate ocial aspirations; in women whose early life had been narred by lack of love and affection, and whose sexual needs after marriage seemed insatiable; and in women vith an inability to accept the animal functions of the body, including secretions and excretions, birth, love, and leath.

FINAL NOTE

Although the importance of sex as a factor in the nausea and vomiting of pregnancy has hitherto escaped the attention of clinical and scientific workers, it has been sensed by non-medical observers. Two fictional works written by well-known lady novelists were recently brought to my notice. In the first (Seymour 1928) the absence of sickness in a pregnancy following an ideal love union was strongly emphasised, while in the second (Ertz 1943) equal emphasis was laid on the persistence of sickness throughout a pregnancy where the wife was not in love with the husband.

Summary

A clinical and statistical investigation of the nausea and vomiting of pregnancy shows that the syndrome may be the physiological expression of an underlying emotional state which may be equated with that of disgust. This view has the merit of covering all the known facts, including those relating to the prevalence of the disorder.

Relevant ætiological characteristics of the personality are disturbed coital functioning, undue mother attachment, and, to a lesser extent, a history of previous dyspepsia.

Relevant factors in the life situation are the frequency of undesired coitus and the physical propinquity of the mother.

These conclusions have important implications for therapy. They indicate the need to supplement physical examination of the patient with investigation into her emotions and life situation.

This investigation owes much to the inspiration and illumination provided by the papers of Dr. J. L. Halliday on psychosomatic medicine. During its preparation I was personally indebted to Dr. G. R. Anderson for useful suggestions and to Mr. J. M. Ross for inquiring into the incidence of sickness in pregnant animals.

CALF PLASMA OR SERUM FOR TRANSFUSION

J. M. Massons
M.D. Barcelona

From the Institute of Medical Research in Barcelona University

The costly business of collecting human blood for transfusion, the difficulties of storing whole blood, and various disadvantages (such as time lost in grouping) in blood-transfusion have led many researchers to seek a substitute for blood. But all have had serious drawbacks.

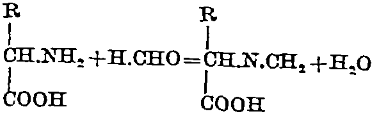
Various attempts have been made to remove the anaphylactogenic properties of animal plasma or serum so as to make it safe for transfusion.

Rosenau and Anderson (1906) used heat and chemical agents, and Doladilhe (1937) tried eliminating a globulin fraction by dialysis. Brodin and Saint-Girons in 1918 successfully injected 500 c.cm. of horse serum into a man, and later (Brodin and Saint-Girons 1939) suggested that transfusion with horse serum might be useful. Kremen et al. (1942) concluded after many attempts that the use of calf plasma was contra-indicated. The use of blood of a lower animal for transfusion in man goes back to 1662 (*Lancet* 1939).

I thought that formol might act on serum anaphylactogens as it did on bacterial toxins and animal venoms, and I found that horse serum treated with formol lost its anaphylactogenic properties after being incubated for some days at 40–45° C (104–113° F) or for a shorter time at a higher temperature. Moreover, formol, in the necessary concentration, at 80–100° C (176–212° F) acted as an antiseptic.

Several workers had already reported the anti-anaphylactic properties of formol. Kendall (cited by Re 1940) and others had shown its inhibiting effect on uterine and intestinal contractions with the Schultz-Dale technique.

The action of formol on amino-acids and proteins has long been known, and Sörensen (1908), using the reaction described by Schiff (1899, 1901)—



$$\underset{\displaystyle\text{COOH}}{\overset{\displaystyle\text{R}}{\text{CH}}}.\text{NH}_2 + \text{H.CHO} = \underset{\displaystyle\text{COOH}}{\overset{\displaystyle\text{R}}{\text{CH}}}.\text{N.CH}_2 + \text{H}_2\text{O}$$

—was able to determine the amino-acids, reckoning on pH deviation resulting from the neutralisation of the amino groups. It is probably this reaction that is responsible for the removal of the anaphylactogenic properties of the proteins, although other substances—e.g., ketene (CH=C=O)—which react with the proteins and block the amino groups, destroy the anaphylactogenic power of animal sera (Goldie and Sandor 1937).

Likewise Zipf and Bartscher (cited by Otto et al. 1938) and Platonov (1940) believe that formol suppresses anaphylaxis by neutralising the biogen amines, especially histamine.

PREPARATION AND PROPERTIES OF CALF PLASMA

To the citrated bovine plasma separated by centrifugation—*for large amounts I use a De Laval blood-separator*—formol is added until a concentration of 0·35% is reached. Five minutes later, to correct the acid deviation resulting from the neutralisation of the amino groups, ammonia is added until a concentration of 0·01% is reached. To avoid further gelification, 0·9% saline or 5% dextrose or doubly distilled water is added until a concentration of proteins 3·7–4·0% is reached. The plasma is then heated over steam and, when it begins to boil at 100° C (212° F), is left to cool to 50° C (122° F). It is filtered to get rid of little clots and small fibrin particles and then put into glass ampoules and tyndallised.

The plasma so treated undergoes slight discoloration and acquires a certain opalescence when viewed against a dark background.

This procedure causes a slight increase in the freezing-point (from −0·48 to −0·56° C) and an important increase in the viscosity. No noteworthy variation is found in the albumin-globulin ratio and in the non-protein nitrogen. Studies are in progress to explain these apparently contradictory changes.

The plasma can be preserved indefinitely at ordinary temperature; already I have samples three years old. It does not agglutinate or hæmolyse human red blood corpuscles. I have never seen any toxic effects due to an excess of formol, probably because part of it combines with the proteins, part with ammonia, and part evaporates on boiling.

The action of formol is the important factor in my method; the heat is only a means to accelerate the reaction and to ensure perfect sterilisation. The truth of this seems to be supported by my above-mentioned experience with the action of formol at 40–45° C and by the fact that in those cases in which the anaphylactogens are destroyed by heat, as in the method of Lenggenhager (1940), new antigenic properties are acquired which *produce anaphylaxis in previously sensitised animals* according to Frimberger (cited by Lang and Schwiegk 1943).

The ammonia is not absolutely necessary; but, if it is not added, the plasma becomes cloudy and its injection is painful. Sodium hydroxide can be used instead of ammonia.

The plasma must be free from hæmoglobin, and as far as possible from lipoids.

By this method the anaphylactogenic properties of the calf plasma are destroyed by physicochemical means whereby the antigens are altered without destroying the physicochemical properties of the plasma.

Studies still unfinished suggest that the degree of destruction of the antigenic power varies according to the level of temperature and the time the formol is acting. Thus at 80° C the formolated plasma changes its colour, as already stated, but retains slight antigenic properties: when repeatedly injected into a rabbit it induces a low titre of precipitins, and it will kill a guineapig with an anaphylactic shock. On the other hand, heated to 100° C, or better to 110° C, it will no longer produce precipitins or anaphylaxis.

EXPERIMENTS

My experiments were done on 70 guineapigs, 40 rabbits, and 2 dogs. I chose young males because Duran-Reynals (1919), Lumière (1933), and Moreira (1925) have shown that pregnant females are resistant towards experimental anaphylaxis.

In an attempt to sensitise the animals, preliminary injections were given to the guineapigs subcutaneously on three successive days or else on alternate days and t test injection intraperitoneally on 10 guineapigs a intracardially in the remaining 40. In the rabbits t preliminary injections were given in the same way in the guineapigs in 10 cases, but in the remaining I used Grove's technique (Sanchez-Cuenca 19 first injection intravenous, second subcutaneous 4-5 later, and test injection intravenous 21 days after t initial dose.

To make sure that the prepared calf plasma (P.C. contained neither complete nor incomplete antigen I carried out the following experiments.

In 40 guineapigs, 10 rabbits, and 2 dogs I gave prel injections of P.C.P. followed by a test injection of P.C.P. *10 other guineapigs and 10 other rabbits I gave* p injections of P.C.P. followed by a test injection of fresh plasm In neither of these sets of experiments was any anaphyla observed. Therefore the P.C.P. contained no antigen.

I next gave 20 other guineapigs and 20 other rabb preliminary injections of fresh plasma, and in order to be s of their sensitisation state I produced in 2 animals a typic anaphylactic shock by injecting them with fresh plasma. The rest of *the animals were treated* with a test injection of P.C.P.; no anaphylactic shock was observed.

In the next experiment I gave preliminary injections of P.C.P. to 8 virgin doe guineapigs and perfused the uterus of each. When P.C.P. was added to the perfusing liquid, no alteration of uterine contractions was observed; but, whe antigen was added, the uterus developed tetany.

My next step proved that P.C.P. 10–20 c.cm. injected intravenously in rabbits had no effect equivalent to that of prote shock.

There followed the investigation of the supposed toxicit of serum proteins by injecting rabbits and dogs, without an harmful result, with quantities of P.C.P. equivalent to a transfusion of 3–5 litres in an adult man weighing 65 kg. (abo 143 lb.).

To test how long P.C.P. remained in the circulatio I bled dogs and measured the blood-pressure (B.P.) an the amount of hæmoglobin, having first taken spec precautions to discount the contraction of liver and spleen by which dogs (but not man) react to hæmorrhage Obviously the injection of liquid into the circulation o a dog with low B.P. will raise the B.P. and reduce the le of hæmoglobin. Conversely, when such injected liq leaves the circulation, the B.P. will fall again and th hæmoglobin become more concentrated.

In contrast to an injection of saline, which produc a merely temporary effect, an injection of P.C.P. maintained its effect for twelve hours in spite of lo continued anæsthesia and small repeated bleedings to determine the amount of hæmoglobin.

I was now ready to experiment on man. I began b giving gradually increasing doses of P.C.P. intravenou to 25 sick or convalescent typhus patients. The init dose was 10 c.cm., and subsequent doses were work up to 300 c.cm. In no case was there any pyrog reaction or the slightest sign of intolerance. In a thousand injections of 100–1000 c.cm., there was never an suspicion of urticaria, which is the most constant sign of serum sickness, appearing in 90% of patients su mitted to large doses of serum given intravenou (Sanchez-Cuenca 1942).

Further experiments led me to conclude that m patients did not become sensitised to calf serum, a matter of importance in obviating future allergy t veal or beef as a food.

THERAPY WITH CALF PLASMA

P.C.P. is given intravenously, somewhat tepid, an preferably slowly; but there is no objection to giving it if necessary, in the same way as a blood-transfusio A few patients complained of transient pain in the vein during the injection of the first 50 c.cm. or so. Apart from that, the only thing to be feared is a rigor after the injection (I had 30 cases in 1000 injections), but with

mproved technique which is being introduced even
risk should disappear.

reated these groups of cases :

ost-hæmorrhagic anæmia, shock from wounds or ileus—
i.e., cases of surgical urgency.
ypoproteinæmias—e.g., lipoid nephrosis, famine œdema,
hepatic cirrhosis.
ehydrated infants, alimentary toxæmia, and wasting.

1 about 200 cases of surgical urgency the results were
arkably good, especially as a prophylactic against
k. For hypoproteinæmia 8 cases of hepatic cirrhosis
e been treated with P.C.P. with results equal to those
ined with human plasma. In the third group of
s Professor Ramos and his co-workers have treated
cases of alimentary toxæmia and a few cases of
ting with P.C.P. with excellent results.

ADVANTAGES OF USING CALF PLASMA

he following are the chief advantages of using P.C.P.
ompared with human plasma :

) The preparation and storage are more economical.
) The plasma can be stored for over a year without
riorating.
) There is no need for refrigeration or any other special
litioning of the plasma.
) Ease of transport.
) P.C.P. can be stored in shops, or in regimental casualty
s in war-time.
) No loss of time in grouping the blood of a wounded man.
) P.C.P. can be injected without any risk. Even in heart-
re it can be given safely, provided that the rate of 2 g.
kg. of body-weight per hour is not exceeded. The only
bt may concern the content of sodium citrate used as an
coagulant ; but this danger has been exaggerated in the
, and the greatest amount given in large doses of P.C.P.
r exceeded 2 g.
) No specialist expert is required to give the transfusion.
body who can give an intravenous injection can administer
P. If intravenous injection is impracticable—e.g., in
ity, peripheral vasoconstriction of shock, previous ampu-
on, extensive burns, and in infants—the plasma can be
n by sternal puncture. The sternal marrow can easily
orb large quantities of fluid. In infants the head of the
a can be used instead of the sternum. This plasma does
harm bone-marrow. Thus, in a moribund infant it was
cted to test its effects, if any, on bone-marrow, and at the
opsy a day later no alteration of the bone-marrow was
nd at the site of injection.
9) Its action most nearly approaches that of blood.

SUMMARY

description is given of the preparation and properties
calf plasma as a substitute for human plasma in
od-transfusion.

xperiments are described which showed that calf
sma so prepared contained no antigens, and that its
ct was not merely temporary like that of saline.

repared calf plasma has been used successfully in
treatment of three types of case : hæmorrhage and
ck, hypoproteinæmia, and dehydration.

wish to thank Prof. F. Garcia-Valdecasas for his friendly
and helpful criticism during my research.

TYPHOID CARRIERS

TREATED WITH PENICILLIN AND SULPHATHIAZOLE

PATHOLOGIST, EPSOM PATHOLOGICAL LABORATORY, LONDON COUNTY MENTAL HEALTH SERVICES

Bigger,[1] in reporting his observations on the synergic action of penicillin and sulphathiazole on *Bact. typhosum* in vitro, made suggestions for treating typhoid fever with these drugs.

In February, 1946, a patient in Bexley Hospital contracted typhoid fever. *Bact. typhosum*, phage type D_1, was isolated from blood culture on the seventh day of the disease. Sulphathiazole 1 g. four-hourly was ineffective. On the twenty-eighth day of the disease the patient's condition was critical ; her temperature was 103·4° F and her pulse-rate 110 per min. A limited amount of penicillin was then available, and treatment with this combined with sulphathiazole was begun. Sulphathiazole 1 g. orally, and about 16,000 units of penicillin intramuscularly, were given every four hours, a total of 387,000 units of penicillin being given in four days. On the thirty-second day of the disease, when this treatment ceased, the temperature had become normal, and remained so except for rises to 99° F on three days. The pulse-rate also fell. At no time was *Bact. typhosum* isolated from the urine or fæces. The impressive clinical improvement coinciding with the administration of so small an amount of penicillin decided us to try the full doses suggested by Bigger, in the treatment of typhoid carriers. An account is now given of the results obtained in two well-established carriers, both of whom regularly excreted *Bact. typhosum*, phage type D_1, in their fæces.

Dosage.—An initial dose of sulphathiazole 2 g. by mouth was followed by 1 g. four-hourly. Penicillin, in doses of approximately 500,000 units dissolved in 10 c.cm. of sterile water, was given intramuscularly at the same time. Treatment continued for eight days in the first case, and seven days in the second.

Bacteriological Investigations.—For a month before treatment and ever since treatment, six samples of every stool passed have been examined, usually one sample in the Bexley laboratory and five at the Epsom Pathological Laboratory. Direct plating was carried out on MacConkey and Wilson and Blair plates, and portions of each sample were passed through enrichment media, either brilliant green in peptone water in three concentrations (1/145,000, 1/250,000, and 1/400,000) and tetrathionate broth followed by plating on MacConkey, or selenite F followed by plating on Wilson and Blair and desoxycholate agar. Magnesium sulphate was given every second or third night to secure regular evacuations. Two samples of a morning specimen of urine were examined by direct plating, one in each laboratory.

Serological Investigations.—Agglutinations to typhoid O and Vi were carried out before treatment and at monthly intervals thereafter.

CASE-RECORDS

Case 1.—A woman, aged 50, admitted to Bexley Hospital on May 17, 1932, had two prophylactic inoculations of T.A.B. vaccine in December, 1940.

---

1. Bigger, J. W. *Lancet*, 1946, i, 81.

−, no agglutination. (±), ±, +, + ±, + +, + + ±, + + +, *increasing degrees of agglutination.*

In September, 1943, in the course of a survey for carriers, her serum gave the following agglutinations (North-western Group Laboratory, L.C.C.): *Bact. typhosum* H 1/320; *Bact. typhosum* O 1/160; and *Bact. typhosum* Vi 1/40.

Typhoid bacilli were isolated from the fæces on four occasions in September and October. Agglutination tests, repeated in August, 1944, gave the following results: *Bact. typhosum* H 1/125; *Bact. typhosum* O 1/125; *Bact. typhosum* Vi 1/2; and against her own organism 1/250. *Bact. typhosum*, phage type D_1, was isolated frequently in February, March, April, and May, 1945.

Cholecystectomy was performed in June, 1945, the patient making a good recovery. Typhoid bacilli were grown from the gall-bladder removed at operation, and after operation the organism was again isolated from the fæces on six occasions in June and July, with one negative result intervening.

During the month's observation before treatment with penicillin and sulphathiazole the patient ran an irregular temperature ranging between 100° and 97° F. This subsided on the third day of treatment, since when the temperature has remained normal. Typhoid bacilli were isolated from the stools passed on thirteen occasions (March 18, 19, 20, April 1, 2, 3, 4, 5, 8, 9, 11, 12, and 15), but not from the five stools passed on March 21, 22, 25 (2 stools), and April 10. Stools were not passed on the days not mentioned.

Treatment was started at 6 P.M. on April 15 and continued for eight complete days, a total of 24,800,000 units of penicillin and 49 g. of sulphathiazole being given. No local or constitutional ill effects attended the treatment. After the second day of treatment typhoid bacilli ceased to be isolated from the stools, and for over 130 days bacteriological examinations of both stools and urine for this organism have been consistently negative.

CASE 2.—A woman, aged 69, admitted to Bexley Hospital on transfer from Canterbury Mental Hospital in April, 1941, had no history of typhoid infection or T.A.B. inoculation, but in April and May, 1945, she had a mild pyrexia for twenty-eight days, which began seven days after being in contact with case 1. In retrospect it now appears that this may have been a mild attack of typhoid fever. On March 26, 1946, on bacteriological examination of the fæces following a serological survey, *Bact. typhosum*, phage type D_1, was isolated.

During the month's observation before treatment *Bact. typhosum* was isolated from the fæces passed on twenty occasions (March 31, April 1, 3, 4, 5, 9, 11, 12, 15, 16, 17, 18, 20, 23, 24, 25, 26, 27, 28, and 29). Stools were not passed on the intervening days. Thus, every stool passed gave a growth of *Bact. typhosum*. *Bact. typhosum* was not isolated on any occasion from the urine.

Treatment with penicillin and sulphathiazole was started on April 29 and continued until the morning of the fifth day, when sulphathiazole by mouth was stopped owing to persistent vomiting and 1 g. of sulphapyridine was given intramuscularly for six successive doses. As the vomiting then ceased, sulphathiazole was resumed orally without further ill effect. A total of 21,420,000 units of penicillin, 36 g. of sulphathiazole, and 6 g. of sulphapyridine were given.

Apart from the bout of vomiting, presumably due to the sulphathiazole, the treatment had no constitutional ill effect, nor was there any local irritation at the site of the injections. *Bact. typhosum* was isolated from the fæces on the second day of treatment, since when for over 116 days intensive bacteriological examination of the morning urine and of every stool passed has failed to isolate t organism.

Agglutination Reactions.—Neither patient showed a fall in the agglutination titres for typhoid H and O, b 8–10 weeks after treatment both showed a definite reduction in typhoid-Vi agglutination titres and a furth reduction after another four weeks (see table I).

DISCUSSION

It is noteworthy that, in both cases reported, *Bact. typhosum* was not isolated from the fæces after the second day of treatment, with the same intensive bacteriological methods as gave positive results on almost every stool before treatment. It seems reasonable to infer that the synergic action of penicillin and sulphathiazole has at least inhibited the growth of *Bact. typhosu* in the alimentary tracts of both these patients, thou a much more extended period of observation is necessary before a safe conclusion can be reached that th carrier state has been cured. Case 1 continued to excre typhoid organisms after cholecystectomy, a not unusu occurrence.

The typhoid H and O agglutination titres after treatment showed no reduction. A much longer interva however, is required before they can reasonably be expected to show a diminution associated with th disappearance of the typhoid organism from the bod of the patient. Nevertheless the reduction of the V titre two months after treatment may be interpreted a indicating that the activity of the organism has cease in these two patients.

In both cases the organism belonged to phage typ D_1, a type not included in those investigated by Bigge

TABLE II—APPEARANCE OF BROTH CULTURES OF *Bact. typhos* PHAGE TYPE D_1, AFTER 48 HOURS' INCUBATION (STANDA INOCULUM)

−, broth clear. (±), ±, +, + ±, + +, increasing degrees o turbidity. Both tubes 6 remained clear after 96 hours *incubation.*

he laboratory the organisms were tested for peni- and sulphathiazole sensitivity by the methods ribed in Bigger's paper, and the results are given ıble II.

is evident, then, that our organisms of phage type exhibit in-vitro sensitivity to sulphathiazole and cillin mixtures similar to those of Bigger's series, it seems reasonable to infer that this sensitivity lso found in the living patient in the two cases stigated.

he bacteriological results obtained in these cases e the question of treating other bacillary infestations he alimentary tract by this method. Should the ergic action of penicillin and sulphathiazole, or other honamide, be as effective in treating dysentery iers as it appears to be in typhoid carriers, the blem of dysentery, in mental hospitals in particular, uld be brought much nearer to an adequate ıtion.

ur experience with these patients shows that the ıtment can be carried out in relatively non-coöperative ıtal patients, even in those showing, as one of ours , much wasting besides profound mental deterioration.

SUMMARY

wo typhoid carriers, one of whom continued to rete *Bact. typhosum* after cholecystectomy, have n treated with penicillin and sulphathiazole on the s suggested by Bigger[1] for typhoid fever.

ntensive bacteriological examination of every stool er treatment failed to reveal the presence of *Bact. hosum* in them for periods of over 130 days in the case, and over 116 in the other.

wo months after treatment both patients showed uced agglutination titres to typhoid-Vi antigen.

hese results encourage the application of this method treatment in a larger number of typhoid carriers to t its effectiveness.

Ve wish to thank Dr. R. Cruickshank for the early work ried out at the North-western Group Laboratory: Dr. A. ix for the phage typing; Prof. J. W. Bigger for much pful information; Surgeon Captain R. G. Henderson, dical superintendent of the Southern Hospital, Dartford, supplying the penicillin; Dr. L. C. Cook, medical super-endent of Bexley Hospital, for his interest; and our hnical staffs, in particular Mr. C. R. Wright and Miss S. ll, for much painstaking coöperation.

YRIDOXINE (VITAMIN B_6) IN EPILEPSY

A CLINICAL TRIAL

J. TYLOR FOX
A., M.D. Camb., D.P.M.
EDICAL SUPERINTENDENT

GLADYS M. TULLIDGE
M.D. Lond., D.T.M. & H.
ASSISTANT MEDICAL OFFICER

LINGFIELD EPILEPTIC COLONY, SURREY

Harriette Chick and her colleagues (1938) observed at pigs deprived of pyridoxine (vitamin B_6) developed pical epileptic fits, and further (1940) that similar s occurred in rats which had been maintained for long riods on a purified synthetic diet supplemented with d-liver oil, pure vitamin B_1, riboflavine, and purified ast-filtrate factor. In either case the fits could be evented or stopped by the addition of pure pyridoxine the diet, and the authors concluded that they were e to deprivation of this vitamin.

There seemed, therefore, to be some justification a clinical trial of pyridoxine in epilepsy. Eight hoolboys, aged 14–15 years and living in the same home, re selected: 2 of them had petit mal only; 2 had tit mal with occasional grand mal; 2 petit mal with re frequent grand mal; and 2 more numerous fits varying type. The cases were selected because of the ularity of the fits, and previous anticonvulsant medication, whether bromide, phenobarbitone, or phenytoin, was continued throughout the experiment.

Our intention was to give one member of each pair 20 mg. of pyridoxine daily for eight weeks, and then the second member of each pair a similar dose in the following eight weeks. When, however, it became apparent that there was no change in incidence of the fits, the daily dose was increased to 100 mg. and the experiment shortened. In the end, 4 boys had received 100 mg. a day for three weeks, 2 had received 20 mg. a day for four weeks and then 100 mg. a day for four weeks, and 2 only 20 mg. a day for eight weeks. There was no evidence of increase or decrease of fits in any case, nor was any other change, mental or physical, noted in any of the boys. So far as this short series of cases is a guide, it seems unlikely that pyridoxine, even in large doses, would be of value in epilepsy.

We are grateful to Messrs. Vitamins Ltd. for supplying us with large quantities of the vitamin, and to Dr. Audrey Baker, of their research laboratory, for her coöperation and suggestions.

PRIMARY DIPHTHERIA OF THE CONJUNCTIVA

REPORT OF TWO CASES

ARCHIBALD R. MILLER
M.D. Glasg., D.P.H.
DIVISIONAL MEDICAL OFFICER,
GLASGOW CORPORATION

DOROTHY E. BLOWER
M.B. Lond.
GENERAL
PRACTITIONER

Two cases of diphtheria affecting the eye only are recorded here, not so much because of the rarity of the condition (Medical Research Council 1930) as because of the rarity of finding the disease being passed from one person to another and affecting the same unusual site in both.

CASE 1.—A girl, aged 3 years, sickened of what was at first thought to be a cold, characterised by nasal discharge and injection of the conjunctivæ. When she was seen by the family doctor four days later the nasal discharge still persisted, and one eye was much inflamed, with very congested conjunctiva, much swollen eyelids, especially the upper one, and a profuse purulent discharge. The child did not appear particularly ill apart from the local condition, and there was no obvious toxicity.

At this stage she was referred to the outpatient department of the Glasgow Eye Infirmary for advice, and there the tentative diagnosis of a diphtheritic infection was made, a swab being taken for bacteriological examination. This was subsequently found to contain corynebacteria, and the child was admitted to a fever hospital while further investigations of the organism were undertaken. These were eventually found to be *C. diphtheriæ* and to be virulent. Although a membrane was reported as being present on the inner aspect of the upper lid its presence was not demonstrated at the fever hospital.

The girl made an uneventful recovery, treatment consisting of antidiphtheritic serum 4000 units and local applications of 'Argyrol' and saline. Repeated cultures from the nasal discharge did not reveal any diphtheritic organisms.

CASE 2.—Four days after the admission of case 1 her brother, aged 5 years, developed a similar condition. The mother, profiting by her previous experience, took him to the doctor at once. The conjunctiva was congested, and the lids were swollen, especially the upper one, but the discharge, though copious, was watery and not purulent. There appeared to be little or no general upset. There was no sign of any discharge or infection elsewhere.

As a precaution, pending further investigation, 4000 units of antidiphtheritic serum was given intramuscularly, and a swab was taken from the eye. The boy was confined to bed. Cultures from the swab revealed the presence of corynebacteria. The patient's local condition appeared now to be improving and his general condition was good. As there

−, no agglutination. (±), ±, +, +±, ++, ++±, +++, increasing degrees of agglutination.

In September, 1943, in the course of a survey for carriers, her serum gave the following agglutinations (North-western Group Laboratory, L.C.C.): *Bact. typhosum* H 1/320; *Bact. typhosum* O 1/160; and *Bact. typhosum* Vi 1/40.

Typhoid bacilli were isolated from the fæces on four occasions in September and October. Agglutination tests, repeated in August, 1944, gave the following results: *Bact. typhosum* H 1/125; *Bact. typhosum* O 1/125; *Bact. typhosum* Vi 1/2; and against her own organism 1/250. *Bact. typhosum*, phage type D_1, was isolated frequently in February, March, April, and May, 1945.

Cholecystectomy was performed in June, 1945, the patient making a good recovery. Typhoid bacilli were grown from the gall-bladder removed at operation, and after operation the organism was again isolated from the fæces on six occasions in June and July, with one negative result intervening.

During the month's observation before treatment with penicillin and sulphathiazole the patient ran an irregular temperature ranging between 100° and 97° F. This subsided on the third day of treatment, since when the temperature has remained normal. Typhoid bacilli were isolated from the stools passed on thirteen occasions (March 18, 19, 20, April 1, 2, 3, 4, 5, 8, 9, 11, 12, and 15), but not from the five stools passed on March 21, 22, 25 (2 stools), and April 10. Stools were not passed on the days not mentioned.

Treatment was started at 6 P.M. on April 15 and continued for eight complete days, a total of 24,800,000 units of penicillin and 49 g. of sulphathiazole being given. No local or constitutional ill effects attended the treatment. After the second day of treatment typhoid bacilli ceased to be isolated from the stools, and for over 130 days bacteriological examinations of both stools and urine for this organism have been consistently negative.

CASE 2.—A woman, aged 69, admitted to Bexley Hospital on transfer from Canterbury Mental Hospital in April, 1941, had no history of typhoid infection or T.A.B. inoculation, but in April and May, 1945, she had a mild pyrexia for twenty-eight days, which began seven days after being in contact with case 1. In retrospect it now appears that this may have been a mild attack of typhoid fever. On March 26, 1946, on bacteriological examination of the fæces following a serological survey, *Bact. typhosum*, phage type D_1, was isolated.

During the month's observation before treatment Bact. typhosum was isolated from the fæces passed on twenty occasions (March 31, April 1, 3, 4, 5, 9, 11, 12, 15, 16, 17, 18, 20, 23, 24, 25, 26, 27, 28, and 29). Stools were not passed on the intervening days. Thus, every stool passed gave a growth of *Bact. typhosum*. *Bact. typhosum* was not isolated on any occasion from the urine.

Treatment with penicillin and sulphathiazole was started on April 29 and continued until the morning of the fifth day, when sulphathiazole by mouth was stopped owing to persistent vomiting and 1 g. of sulphapyridine was given intramuscularly for six successive doses. As the vomiting then ceased, sulphathiazole was resumed orally without further ill effect. A total of 21,420,000 units of penicillin, 36 g. of sulphathiazole, and 6 g. of sulphapyridine were given.

Apart from the bout of vomiting, presumably due to the sulphathiazole, the treatment had no constitutional ill effect, nor was there any local irritation at the site of the injections. *Bact. typhosum* was isolated from the fæces on the second day of treatment, since when for over 116 days intensive bacteriological examination of the morning urine and of every stool passed has failed to isolate organism.

Agglutination Reactions.—Neither patient showed a fall in the agglutination titres for typhoid H and O, but 8–10 weeks after treatment both showed a definite reduction in typhoid-Vi agglutination titres and a further reduction after another four weeks (see table I).

DISCUSSION

It is noteworthy that, in both cases reported, *Bact. typhosum* was not isolated from the fæces after the second day of treatment, with the same intensive bacteriological methods as gave positive results on almost every stool before treatment. It seems reasonable to infer that the synergic action of penicillin and sulphathiazole has at least inhibited the growth of *Bact. typhosum* in the alimentary tracts of both these patients, though a much more extended period of observation is necessary before a safe conclusion can be reached that the carrier state has been cured. Case 1 continued to excrete typhoid organisms after cholecystectomy, a not unusual occurrence.

The typhoid H and O agglutination titres after treatment showed no reduction. A much longer interval, however, is required before they can reasonably be expected to show a diminution associated with the disappearance of the typhoid organism from the body of the patient. Nevertheless the reduction of the Vi titre two months after treatment may be interpreted as indicating that the activity of the organism has ceased in these two patients.

In both cases the organism belonged to phage type D_1, a type not included in those investigated by Big

SUMMARY

wo typhoid carriers, one of whom continued to ete *Bact. typhosum* after cholecystectomy, have treated with penicillin and sulphathiazole on the s suggested by Bigger[1] for typhoid fever.

ntensive bacteriological examination of every stool r treatment failed to reveal the presence of *Bact. iosum* in them for periods of over 130 days in the case, and over 116 in the other.

wo months after treatment both patients showed uced agglutination titres to typhoid-Vi antigen.

hese results encourage the application of this method treatment in a larger number of typhoid carriers to its effectiveness.

Ve wish to thank Dr. R. Cruickshank for the early work ried out at the North-western Group Laboratory; Dr. A. ix for the phage typing; Prof. J. W. Bigger for much pful information; Surgeon Captain R. G. Henderson, dical superintendent of the Southern Hospital, Dartford, supplying the penicillin; Dr. L. C. Cook, medical super- endent of Bexley Hospital, for his interest; and our hnical staffs, in particular Mr. C. R. Wright and Miss S. ll, for much painstaking coöperation.

YRIDOXINE (VITAMIN B_6) IN EPILEPSY

A CLINICAL TRIAL

J. TYLOR FOX
A., M.D. Camb., D.P.M.
DICAL SUPERINTENDENT

GLADYS M. TULLIDGE
M.D. Lond., D.T.M. & H.
ASSISTANT MEDICAL OFFICER

LINGFIELD EPILEPTIC COLONY, SURREY

Harriette Chick and her colleagues (1938) observed at pigs deprived of pyridoxine (vitamin B_6) developed pical epileptic fits, and further (1940) that similar s occurred in rats which had been maintained for long riods on a purified synthetic diet supplemented with d-liver oil, pure vitamin B_1, riboflavine, and purified ast-filtrate factor. In either case the fits could be evented or stopped by the addition of pure pyridoxine the diet, and the authors concluded that they were e to deprivation of this vitamin.

There seemed, therefore, to be some justification r a clinical trial of pyridoxine in epilepsy. Eight hoolboys, aged 14–15 years and living in the same home, ere selected: 2 of them had petit mal only; 2 had tit mal with occasional grand mal; 2 petit mal with ore frequent grand mal; and 2 more numerous fits varying type. The cases were selected because of the gularity of the fits, and previous anticonvulsant medication, whether bromide, phenobarbitone, or phenytoin, was continued throughout the experiment.

Our intention was to give one member of each pair 20 mg. of pyridoxine daily for eight weeks, and then the second member of each pair a similar dose in the following eight weeks. When, however, it became apparent that there was no change in incidence of the fits, the daily dose was increased to 100 mg. and the experiment shortened. In the end, 4 boys had received 100 mg. a day for three weeks, 2 had received 20 mg. a day for four weeks and then 100 mg. a day for four weeks, and 2 only 20 mg. a day for eight weeks. There was no evidence of increase or decrease of fits in any case, nor was any other change, mental or physical, noted in any of the boys. So far as this short series of cases is a guide, it seems unlikely that pyridoxine, even in large doses, would be of value in epilepsy.

We are grateful to Messrs. Vitamins Ltd. for supplying us with large quantities of the vitamin, and to Dr. Audrey Baker, of their research laboratory, for her coöperation and suggestions.

PRIMARY DIPHTHERIA OF THE CONJUNCTIVA

REPORT OF TWO CASES

ARCHIBALD R. MILLER
M.D. Glasg., D.P.H.
DIVISIONAL MEDICAL OFFICER,
GLASGOW CORPORATION

DOROTHY E. BLOWER
M.B. Lond.
GENERAL
PRACTITIONER

Two cases of diphtheria affecting the eye only are recorded here, not so much because of the rarity of the condition (Medical Research Council 1930) as because of the rarity of finding the disease being passed from one person to another and affecting the same unusual site in both.

CASE 1.—A girl, aged 3 years, sickened of what was at first thought to be a cold, characterised by nasal discharge and injection of the conjunctivæ. When she was seen by the family doctor four days later the nasal discharge still persisted, and one eye was much inflamed, with very congested conjunctiva, much swollen eyelids, especially the upper one, and a profuse purulent discharge. The child did not appear particularly ill apart from the local condition, and there was no obvious toxicity.

At this stage she was referred to the outpatient department of the Glasgow Eye Infirmary for advice, and there the tentative diagnosis of a diphtheritic infection was made, a swab being taken for bacteriological examination. This was subsequently found to contain corynebacteria, and the child was admitted to a fever hospital while further investigations of the organism were undertaken. These were eventually found to be *C. diphtheriæ* and to be virulent. Although a membrane was reported as being present on the inner aspect of the upper lid its presence was not demonstrated at the fever hospital.

The girl made an uneventful recovery, treatment consisting of antidiphtheritic serum 4000 units and local applications of 'Argyrol' and saline. Repeated cultures from the nasal discharge did not reveal any diphtheritic organisms.

CASE 2.—Four days after the admission of case 1 her brother, aged 5 years, developed a similar condition. The mother, profiting by her previous experience, took him to the doctor at once. The conjunctiva was congested, and the lids were swollen, especially the upper one, but the discharge, though copious, was watery and not purulent. There appeared to be little or no general upset. There was no sign of any discharge or infection elsewhere.

As a precaution, pending further investigation, 4000 units of antidiphtheritic serum was given intramuscularly, and a swab was taken from the eye. The boy was confined to bed. Cultures from the swab revealed the presence of corynebacteria. The patient's local condition appeared now to be improving and his general condition was good. As there were no other children in the house, it was decided to keep him at home. In due course the bacteriologist reported that these organisms too were *C. diphtheriæ* and were virulent on biological test. By this time the eye had returned to normal and the patient seemed well.

There seems to be little doubt that the second patient was infected from his sister. There were no other cases of diphtheria of any kind at that address, and the patients did not attend any school or day-nursery. There was remarkably little toxic absorption from the conjunctiva. Neither child had any complications, and there was only a moderate rise in temperature. In case 1 the temperature was 100·2° F on admission to hospital and normal by the next day, and in case 2 no rise of temperature was found.

Harries and Mitman (1940) point out that the toxicity of non-respiratory diphtheria, though variable, is usually slight, and that diphtheria of the conjunctiva may be followed by rapid destruction of the globe. No suggestion of this was seen in either of these cases, but both were relatively quickly brought under treatment. *We have not been able to find in the literature* any record of the disease spreading from one patient's eye to that of another. The Medical Research Council (1923) reported that, though diphtheritic conjunctivitis was formerly considered fairly common, most modern writers agreed that conjunctivitis caused by true virulent diphtheria bacilli was rare.

PERITONEAL NODULES OF UNKNOWN ÆTIOLOGY

HASSAN IBRAHIM
M.B., M.Ch.
SURGICAL TUTOR, KASR EL AINI HOSPITAL, CAIRO

MILIARY nodules of the peritoneum are sufficiently rare to be worth recording.

A married woman, aged 29, with no children, had had frequent attacks of tonsillitis up to the age of 8 years, once complicated by quinsy. She had never had acute rheumatism, chorea, or any other rheumatic manifestation. She had had an attack of gastric pain accompanied by vomiting and hæmatemesis, lasting twenty-four hours, at the age of 8 years, and a similar but milder attack two years later. At the age of 19 she had sciatica.

Two years ago she began to have epigastric pain, occasional vomiting, constipation, and lassitude. She had periodic exacerbations of the pain lasting 2–4 days, alternating with periods of relative freedom. Continuous slight fever, ranging from 99° F to 102° F, persisted throughout. The symptoms were worse during the summer and tended to improve during the winter. She had always been thin, and lost 8 kg. during the illness.

Various conditions had been suspected and treated—e.g., gall-bladder disease, liver disease, renal colic, spastic colitis, and appendicitis—but none had been confirmed. In the spring of 1943 she had two severe attacks of generalised abdominal pain accompanied by high fever, up to 103° F, and aching in the limbs.

On examination, the heart and lungs were normal. A definite tenderness over McBurney's point and over the whole right iliac fossa led to a diagnosis of appendicitis and operation.

Operation.—The abdomen was opened through a low right paramedian incision. The terminal coils of the ileum, especially along its mesenteric attachment, were studded all over with hundreds of white nodules, about 2 mm. in diameter. There were also nodules on both aspects of the mesentery. The condition stopped just short of the cæcum, which was normal. The nodules were scattered singly and in bunches of 10 or more, resembling collections of small pearls. Though sessile, they were only slightly adherent to the intestine and could easily be picked off with forceps leaving no bleeding points behind. The parietal peritoneum appeared to be quite free from nodules, and neither fluid nor congestion was present. No other abnormality was found, and the stomach, duodenum, gall-bladder, bile-ducts, and liver appeared normal. The appendix was removed, and some of the nodules were taken for biopsy.

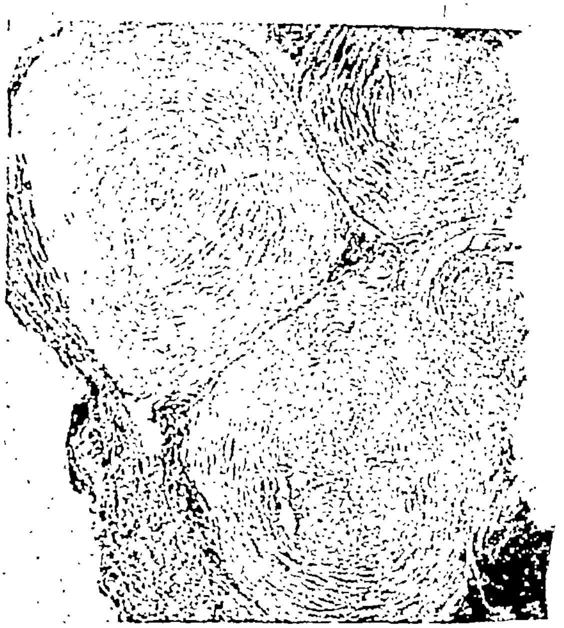

Fig. 1—Conglomerate mass of nodules with vascular fibrous tissue in between. (Low power.)

Histological Examination.—The first sections showed conglomerate nodules of whorled fibrous tissue (fig. 1). One of the larger nodules was fibrous, its centre consisting of hyaline fibroid tissue in concentric layers with empty fusiform spaces between the fasciculi (fig. 2). The periphery of the nodule consisted of fibrous tissue which was fairly vascular, sometimes hæmorrhagic, and moderately cellular. A peripheral round-cell infiltration of chronic inflammatory type was also seen (fig. 3). *A single group of endothelioid* cells, similar to an Aschoff body, was present in the outer cortex of the nodule, embedded in vascular fibrous tissue (fig. 4) and closely related to blood-vessels. Smaller fibrous nodules were lying close together, with delicate cellular fibrous tissue between

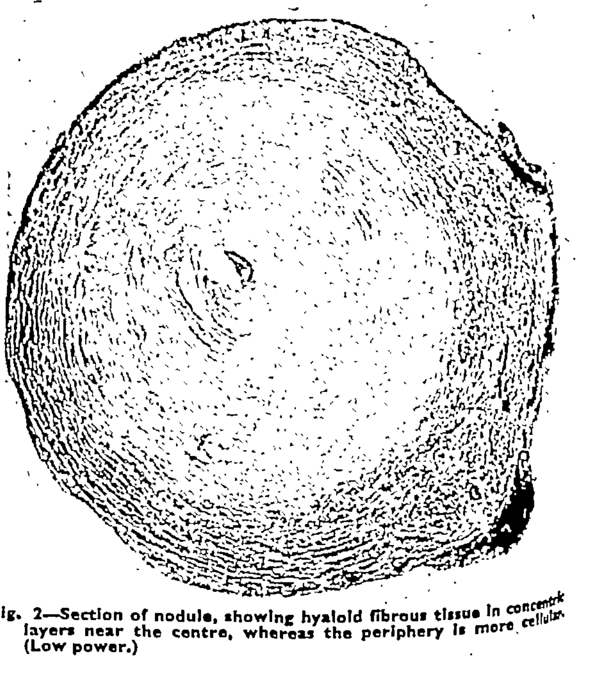

Fig. 2—Section of nodule, showing hyaloid fibrous tissue in concentric layers near the contre, whereas the periphery is more cellular. (Low power.)

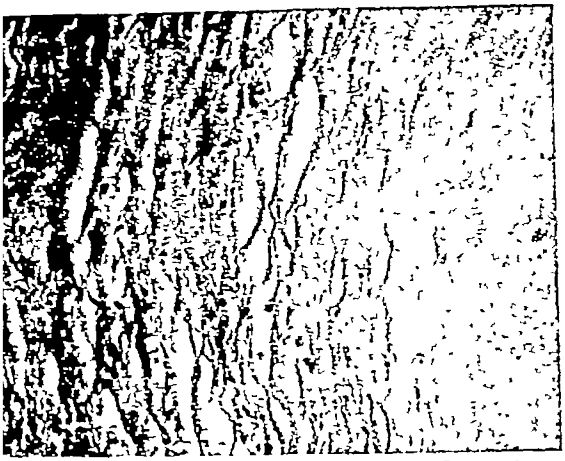


3—Periphery of nodule, showing the more cellular fibrous tissue. (High power.)

n. The nodules were covered with a single layer of flat sa cells. Careful search failed to reveal any bilharzia ova emnants of ova in any of the many sections examined. a whole, the histological appearance suggested a chronic -pyogenic inflammatory condition.

DISCUSSION

)nly scanty references to nodular lesions of the itoneum have been published. Haythorn (1933) ssifies nodular lesions of the peritoneum as:

Tuberculous.

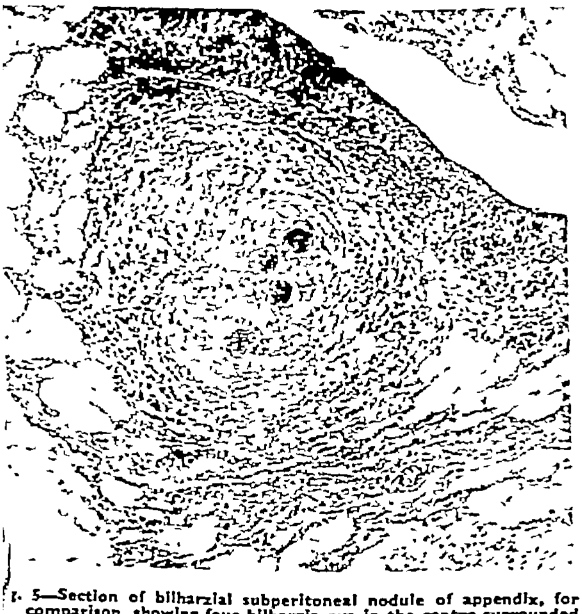
Pseudotuberculous (due to various bacilli).

Syphilitic.

Due to fungus infections.

Foreign-body granulomas due to (*a*) animal parasites, such as bilharzia, *Entamœba histolytica*, or *Oxyuris vermicularis*; (*b*) extravasated blood; (*c*) gelatinous substances, including ruptured pseudomucinous cysts and extraneous substances; (*d*) oils and free fats; (*e*) extruded gastric and intestinal contents; (*f*) extraneous foreign bodies, such as sutures, &c.

) Neoplasms, such as carcinoma, sarcoma, melanosarcoma, Hodgkin's disease, &c.



5—Section of bilharzial subperitoneal nodule of appendix, for comparison, showing four bilharzia ova in the centre surrounded by several layers of endothelioid cells and a peripheral lymphocyti and fibroblastic reaction.

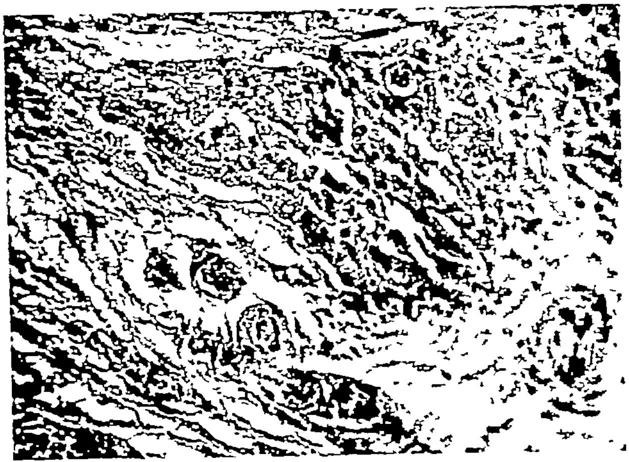


Fig. 4—Aschoff's nodule found in cellular periphery of a fibrous nodule. (High power.)

Except bilharziasis, none of these conditions resembles the present findings, either macroscopically or microscopically. Even bilharziasis can probably be excluded. Bilharzial nodules are usually firmly adherent and resist stripping when picked up with the forceps. They affect the large intestine rather than the small, and are accompanied by signs of bilharzial infection of the mucosa. Bilharzial dysentery, with diarrhœa, tenesmus, the passage of blood and mucus, and with ova in the stools, is usual in such cases. All these features were absent in the present case.

The strongest evidence against bilharziasis is the fact that no trace of ova or remnants of ova were found in any of the serial sections examined. Remnants of ova —i.e., the chitinous capsule and spine—are very persistent and are always found in bilharzial lesions, however old they may be (fig. 5). The Aschoff bodies found in this case have never been seen in bilharzial conditions.

Bilharziasis is only accompanied by fever for a short time after the initial stage of infection and never causes continuous fever lasting for years. Careful inquiry failed to reveal any exposure to bilharzial infection in this case.

The similarity of the lesions to Aschoff's nodules suggested the possibility of a rheumatic ætiology. Rheumatic peritonitis has often been described, usually in association with arthritis and carditis, and the subject has recently been discussed by Berger (1945). In the present case the absence of all other rheumatic manifestations, the fact that the lesions were limited to the peritoneum, and the doubtful interpretation of the histological findings, do not justify the condition being definitely designated as rheumatic.

SUMMARY

In a woman of 29 years with recurrent abdominal pain and fever for two years operation revealed an unusual miliary nodular condition of the peritoneum especially over the terminal ileum.

The nodules consisted of whorls of fibrous tissue, and some contained collections of endothelioid cells resembling Aschoff bodies. No bilharzia ova were found.

The findings pointed to a chronic non-pyogenic inflammatory condition, but no cause could be determined.

I am indebted to Dr. M. Sorour, professor of pathology in the Fouad 1st University of Cairo, for his full report on the histological sections; Major G. D. Morgan, R.A.M.C., for similar assistance; and Brigadier Evan Bedford for his guidance in reporting the case.

THE LANCET

LONDON: SATURDAY, SEPT. 7, 1946

Medicine, Population, and Food

IN the past, populations have been held in check disease, famine, and war, and to a lesser extent contraception and infanticide. Of these factors sease has probably been the most important. estilences, such as the plague of Justinian (of which ROCOPIUS[1] has left so accurate a record), the Black eath, cholera, and influenza have slain their millions; nd of even greater importance have been the ever-resent diseases, such as pneumonia, gonorrhœa, and alaria. There is evidence that the decline and fall Greece and Rome were accelerated, even if they ere not initiated, by malaria: the sequence of events familiar to everyone who has lived in the tropics—eforestation by man and his goats, soil erosion, vampy valleys, and mosquito breeding. Today, in frica, India, and the Far East, malaria rivals and ossibly outstrips malnutrition as a cause of mortality mong young children, while in adults it lowers esistance to other infections: an estimate on the onservative side suggests that every year at least million persons are killed by the various species of lasmodium. Pneumonia, too, is an important cause f death among primitive peoples and especially mong negroes in Africa: it appears in epidemic almost every year, with the advent of the cooler eather. Gonorrhœa, by causing sterility in both exes, has been one of the primary causes of a low irth-rate. Even in war, despite the growing deadliess of offensive weapons and the increasing effectiveess of preventive measures, deaths from disease have lways exceeded those from enemy action, while the esults of disease far outlast those of bullet and bomb. ermany and the whole world are still suffering, s ALDOUS HUXLEY[2] has pointed out, from the isease and devastation wrought by the Thirty Years Var (1618–48). Only the atom bomb seems comarable in its lethal effects to that of pathogenic arasites.

If we wish, we can now do much to decrease the nfections which have hindered increase of population. or the first time in the world's history we possess emedies capable of reducing malaria, pneumonia, nd gonorrhœa. In 'Paludrine,' it is said, we have at ast a true causal prophylactic for both malignant nd benign tertian malaria, as well as a curative gent in advance of any previously known: it s cheap, easy to make in large quantities, and of ery low toxicity, and to the feminine half of the orld it offers the huge advantage of leaving the omplexion unaffected. By means of penicillin and he sulphonamides we can now reduce the death-rate rom pneumonia and can go far to prevent sterility rom gonorrhœa. Even some of the most primitive aces are already asking for large supplies of hese remedies as a panacea, while the sulphonmides have become so popular in West Africa that a profitable trade has developed in substitute tablets made from such unpromising materials as chalk, clay, or plaster-of-paris. Penicillin has the additional advantage that it is (in proper dosage) effective against syphilis, yaws, and tropical ulcer; and even localised causes of mortality, like typhus and trypanosomiasis, can now be controlled, either by chemotherapy or by using the newer insecticides. We still lack effective remedies against virus diseases and tuberculosis, but the progress of the last ten years encourages hope for the next ten.

There remains, in the form of malnutrition, one check to human life which could be even more deadly in the future than it has been in the past. Before the war we were already all too familiar in western civilisation with the huge sprawling city which, in the words of LEWIS MUMFORD,[3] had ceased to be a metropolis and had become a megalopolis and a parasitopolis: but most of us were less well aware that in parts of China, India, and Africa population was also, as in Europe, far in excess of indigenous food. Though local famines were sometimes reported, less was heard about the fact that even before the war 90% of people in the tropics were living on a diet which, though it might be adequate in calories for most of the year, was almost always deficient in proteins and vitamins of the B complex, while for some months, during what was euphemistically called "the hungry season," it was deficient in everything. Over 1000 million people were getting, on the average, less than 2250 calories daily.[4] Today, nobody in these islands is likely to forget that the shadow of a hungry season has spread from the tropics to the whole of the old world. If all the peoples of the world are to be properly fed, and if we add annually to their number all those who would previously have died from malaria, pneumonia, typhus, or trypanosomiasis, and all those who would never have been born if their parents had still been suffering from gonorrhœa or malnutrition, we shall need tremendous increases in the production and transport of essential foodstuffs. Such changes can be ensured only by a world authority empowered, if need be, to adjust national interests to international needs. Meanwhile, would it not be well for working parties, each consisting of a doctor, an agriculturist, a food technologist, a nutritionist, and a welfare worker, to visit not only the West Indies (as proposed by PLATT[5]) but every region in the world to report precisely on the prevailing conditions? Even on the most casual survey it is obvious that there are many areas where new and useful crops might be cultivated if only local governments and their agricultural departments could be stimulated to turn official memoranda into positive action. Similarly the example of the "food-yeast" factory, established for the benefit of the Caribbean zone, might be copied elsewhere. The whole question, in fact, of the synthesis of vitamins and essential amino-acids by laboratory methods on a manufacturing scale demands immediate attention.

Sir JOHN ORR's report to the conference which opened at Copenhagen on Sept. 2 proposes the establishment of a World Food Board. In the task

Reviews of Books

A Textbook of Forensic Pharmacy

THOMAS DEWAR, PH.D., B.PHARM. Lond., PH.C., barrister-at-law, examiner to the Pharmaceutical Society of Great Britain. London: Edward Arnold. Pp. 253. 10*s.* 6*d.*

SUCH a book as this has for long been urgently needed, for no-one could pretend that the laws controlling the preparation, sale, and use of poisons are concise or readily accessible. Yet the pharmaceutical chemist, the toxicologist, and the barrister all need more detail than can be obtained from the textbooks of forensic medicine or pharmacy. In this book every conceivable detail has been handled by an expert who knows its significance in practice, and the text defies criticism in this respect. The dullness which is inevitable in any long statement of the law is leavened by such charming quotations as these:

> Here phials in nice discipline are set,
>   There gallypots are rang'd in alphabet,
> In this place, magazines of pills you spy;
>   In that, like forage, herbs in bundles lie.
>
> GARTH, *The Dispensary*, Canto 1.
>
> Don't rely too much on labels,
>   For too often they are fables.
>
> SPURGEON, *Salt Cellars.*

Extensive footnote references to law and free use of practical examples make this a real yet easily handled compendium of reference. Its field embraces the forensic aspects of such widely diverse subjects as pure pharmacy, institutional dispensing, the Shop Acts, the Food and Drugs Act, and the Venereal Disease Act. Though intended primarily for the pharmaceutical student, the book is certain to have a wide circulation in both medical and legal circles.

The Physiological Basis of Medical Practice

(4th ed.) C. H. BEST, C.B.E., M.D., D.SC., F.R.S.; N. B. TAYLOR, M.D., University of Toronto. London: Baillière. Pp. 1169. 55*s.*

THE doctor—whether houseman, practitioner, consultant. or teacher—as well as the student, will continue to be attracted by this magnificent work. Best and Taylor has become a classic, providing a link between the laboratory and the wards. The authors animate the relatively dry bones of preclinical studies by emphasising their practical application to future clinical work; they bridge the gap when the student enters the wards; and for the houseman too, acutely aware of his lack of understanding, they explain the disorders of function which are perplexing him. Even the teacher at the bedside will find here a better way of giving the answer to many an anticipated question, and the sections on morbid physiology offer the basis for much intelligent research. Clinically the book is accurate and up to date and conforms to modern teaching. The extensive bibliography and the references are conveniently grouped under chapter headings at the end of the book. This edition appears in new form: double columns are said not only to save space but to make easier reading; but this seems doubtful.

A Complete Outline of Fractures, including Fractures of the Skull

(2nd ed.) J. GRANT BONNIN, M.B. Melb., F.R.C.S., late first assistant to the Injury Clinic, West London Hospital; recently surgeon in charge, fracture "A" centre, E.M.S.; major R.A.M.C. London: W. Heinemann. Pp. 658. 30*s.*

UNDER this promising title, Mr. Bonnin has really written a comprehensive textbook of fracture surgery. Almost 200 pages are given to general considerations, and the remainder to descriptions of the fractures of the various bones, including a brief but satisfactory chapter on those of the face and jaw by Mr. J. H. Barron. Writing primarily for students, Mr. Bonnin has selected carefully the material needing specially detailed description, and so has been able—in his chapters on ankle fractures, for instance—to expand and elaborate many of the principles applicable to fractures in general. Simple and complex methods of treatment are detailed and no examiner could cavil at the methods recommended. Moreover, by indicating and giving the reasons for his preferred methods, the author sets a personal stamp on his work: the book is no "rehash" of more extensive works on the subject. He says in his introduction that he writes with memories of the inadequacy of his student textbooks. This book is certainly not inadequate: in an age of dehydrated textbooks his full description is refreshing, and the reasonable student will not grudge the few extra hours its reading entails.

Dr. J. Ross Mackenzie's little handbook, *Practical Anæsthetics* (2nd ed., Baillière, Pp. 172, 10*s.* 0*d.*), for students and hospital residents, has been revised throughout. As in the first edition, teaching is primarily given to the fundamentals of practical anæsthesia. Many matters of no direct practical interest to the beginner are reviewed, but junior anæsthetists will find the book useful.

New Inventions

SIMPLE APPARATUS FOR MICRO-SUBLIMATION

THE apparatus here described was introduced by us in the chemical investigation of cases of *toxæmia.* Developments of micro-chemistry, in which the unit is a millionth of a gramme, suggested that it might be possible to identify some of the toxins which are present in such minute quantities that they have defied analysis. Many such substances are adsorbed by fine activated charcoal, and if this is given by the mouth and subsequently recovered the substances can be extracted from the charcoal. But included with the toxins are various alkaloidal and resinous substances, which the patient may have taken medicinally. It is in the separation of these fractions that this apparatus is so useful.

In general the micro-oven follows the form of the apparatus of Kempf. It consists of a brass block (see figure), which was a model engine casting. Two tubes of copper were turned to a driving fit, and driven into the cylinder cavities. At the suggestion of my assistant, Mr. W. G. King, one tube was made to project three inches and was tapered in the part outside the brass block. This part of the tube was marked off at half-inch intervals. A thermometer is fitted in the second bore-hole. The block was heated on an asbestos mat over a gas flame. A graph was made showing the temperature at each mark corresponding to standard temperatures of the block—say 200°, 250°, and 300° C. The temperature will decline from the block to the end of the long tube, so that different parts of the tube will be at different temperatures. The graph was made on half-inch paper, and thus the graph corresponded to the three inches of the tube.

A mixture to be separated is placed in a glass tube, closed at one end, and this is inserted into the graduated copper tube, so that the closed end of the glass tube is at the middle of the block, and it is marked at the end. On heating, sublimation will occur at intervals along the glass tube; and by laying the tube on the graph the approximate sublimation temperature can be found. The fractions can then be separated by the scratch and hot wire method. A scratch is made on the glass tube and the fracture is led round the tube by applying a hot bent-iron wire. Each fraction, so cut off, is then examined separately.

C. LOVELL, M.C., M.D. Lond.

Bethlem Royal Hospital.

bcutaneously and intradermally, using hollow edles, they reached the interesting conclusion that munity to vaccinia resulted only when there was local reaction which included the formation of a sicle, the latter being due presumably to back akage of the inoculum along the needle track.

Very little has been recorded in this country about accination by multiple pressure or intracutaneous rick, although both these methods are older than the ratch technique, and one of them was probably sed by JENNER. Most of the published papers deal ith the vaccination or revaccination of adults, and s regards infant vaccination there is but little in rint about any of the techniques. DUDLEY[5] found hat substitution of multiple pressure for the scratch method reduced sickness and disability due to vaccination and revaccination among the adolescent entrants o a naval school. PARISH,[6] however, noted that when t was used for the primary vaccination of a group of dults nearly a quarter of them had severe local eactions. It has been stated[3] that the results of evaccination by intracutaneous prick are easier to ead because local reaction due to trauma does not bscure the so-called immune and vaccinoid types of response. Another advantage attributed to vaccination by prick or pressure instead of by scratch is that no dressing is required; but this has not been the experience of at least one observer.[6]

It is by no means certain that trauma of the skin during insertion is the only cause, or indeed the chief cause, of severe local reactions. Although the bacterial content of vaccine lymph can be reduced to a low level by proper methods of manufacture, it remains a more or less unknown factor in any given vaccination; moreover observations with purified preparations of vaccinia virus suggest that local reactions still occur when bacteria are absent. Other factors of undetermined importance in this respect are the concentration of virus in the lymph and the immunity response of the individual. Touching on this there are the remarks of CRAIGIE as quoted by TULLOCH[7] in 1934: "the magnitude and endurance of the immunity response is primarily a question of the individual and his capacity to respond—not of vaccination technique. The amount of seed and the area of skin involved would seem to be of minor importance as regards immunity, so that nothing is to be gained by making either too great. If they are reduced to a minimum the developing immunity will be better able to overtake the proliferating virus, thus minimising reaction and the risk of sequelæ." This implies that minimal trauma during insertion may shorten the duration of the reaction and thus lessen its severity.

It would be well worth making some practical comparative studies of the three main methods of vaccination—dermal scratch, multiple pressure, and intracutaneous prick—on a scale big enough to give the results statistical significance. Teachers of vaccination at the medical schools might be able to undertake such studies in connexion with the vaccination of infants. For an investigation of the vaccination and revaccination of adults Service medical departments would be better placed.

Standards and Stampedes

THE victims of the housing shortage have reached the stage of exasperation. Squatters are moving into military camps in many parts of the country and taking joyful possession. It will be hard for the authorities to sort out those deserving priority, but the movement as a whole must command sympathy and understanding, in spite of the obvious embarrassments it creates. There is one risk, however, which needs to be watched with great care: that the shortage will lead to a lowering of accepted standards in housing, especially standards of amenity and hygiene. To meet emergency conditions minimum sanitation may do well enough for a time, but it is fatally easy to slide downwards, by allowing the temporary to become permanent and even to be slipshod about permanent building. The London County Council have set themselves high standards of amenity in the homes they propose to build. They have determined to keep abreast with modern developments in construction and fittings. Other areas would do well to follow this lead.

The question of accommodation is more serious and difficult. Both the Dudley Report and the Housing Manual of the Ministry of Health, while urging local authorities to study the actual needs of families in their areas, recommend that, for the time being at least, they should continue to provide three-bedroom houses as their main programme. Some doubt has been cast on the wisdom of this policy. Thus in the *Times* a correspondent asks, "Do we want tens of thousands of three-bedroomed houses? A three-bedroomed house is too big for a newly married couple:" and he goes on to speak of the "amount of waste space that is being built with our hard-pressed building resources." If we leave aside the special requirements of single persons and the aged, we can concentrate attention on the family. It is estimated that about 80% of families have no more than two children, and the "average" three-child family is represented by about 10%. On the face of it the *Times* correspondent seems right in saying that "continued overproduction of standard-sized houses is wasteful of resources," but he is on less solid ground in adding that "this must seriously retard the economic possibilities of any increase in the child population." The suggestion that the child population might be increased by reducing the number of bedrooms in the family house might be true, if family limitation were merely a matter of economics, but it is possible that other factors, including lack of bedrooms, act as a more direct brake on size of family. At any rate houses with only one or two bedrooms offer no encouragement to young married couples to be fruitful and multiply.

The story is not so simple as this. Indeed, it is doubtful whether the talk about waste space is well founded. Between 1919 and 1934 some 42% of the houses built were within the range of workers' incomes: a further 40% might, at some sacrifice, have been bought by the better off artisans; and the remainder were beyond their reach. Between 1934 and 1939 only 41% of the houses built (apart from slum clearance) were genuine working-class houses. In other words, a great host of three-bedroomed houses built between the wars were not for

of feeding people better, the limiting factor at present is, he believes, not the physical capacity to produce enough food but the ability of nations to bring about the complex economic adjustments necessary to make adequate production and distribution possible.[4] To this the board would devote its efforts; and, given enough good will, the results might prove astonishing within our lifetime.

Activation of Skin Grafts

MODERN plastic surgery has firmly upheld THIERSCH's dictum that a skin graft takes better on an active or "excited" raw area than on one freshly prepared from normal quiescent tissue. Freshly cut tissue normally has to pass through a latent period of several days before proliferation becomes really active, and this latent-period is eliminated when grafts are transplanted to (for example) healthy granulations. "When a surgeon takes up his knife to cut into normal tissues," says PEYTON ROUS,[1] "everything has been prepared for operation except the structures immediately concerned." If graft beds are the better for being in an active state, is it not likely that the grafts themselves would benefit by activation?

ROUS has investigated this problem. Clipped rabbits' skin was painted with a mixture of turpentine and acetone to induce epidermal proliferation; and after a few days the epidermis, normally one or two cell-layers deep, had thickened five- or six-fold and was vigorously dividing. Grafts so activated were compared with those cut from normal quiescent skin, by grafting both simultaneously in patchwork arrangement to rather poorly vascular beds freshly cut down to the deep corium of the skin in the lumbar region. Histological analysis revealed the following credit and debit accounts. Activated grafts are easier to cut and handle and are less inclined to fold and contract. When they heal, they do so more rapidly and securely than normal skin; the donor areas are more quickly resurfaced and, if need be, yield more promptly a second crop of grafts. But there are grave disadvantages. The demands of hyperplastic skin for nourishment are naturally greater than those of normal quiescent skin, and a number of hyperplastic grafts promptly die when transplanted to poorly vascular beds, while their normal neighbours quietly "sit out time." Sometimes the hyperplasia itself is troublesome, since the deep follicle epithelium of an activated graft sometimes creeps between graft and bed and begins to infiltrate the underlying tissue.

ROUS's observation of the necrosis of activated grafts on poorly vascular beds is interesting in the light of MEDAWAR's guess[2] that a really thick graft should be deliberately deactivated, in order to lower its metabolic demands during the critical stage of vascularisation. The deactivation is simply a matter of allowing the graft surface to remain at room temperature instead of at body temperature, as when thick gauze or cotton-wool pads are put over it to maintain pressure. In plastic surgery uses may be found for both activation and deactivation. The former might fill the bill for pinch grafts transplanted *to highly active granulations, for pinch grafts are* never used unless speedy epithelial spread is needed. Deactivation might be the rule when full thicknes grafts are to be transplanted to poorly vascular, freshly cut, beds—for example, on the back of the hand. But for the ordinary run of skin-graftin there can be no question of adopting either activation or deactivation as a routine.

How to Vaccinate

INFANT vaccination against smallpox will soo become voluntary, and opinions are divided abou the probable result of this change. Some think that the vaccination of about a third of the popul tion during the first year of life, achieved under th existing laws, will be maintained or even increas when medical services are extended under the n Bill. Others hold that hardly any infants will vaccinated when compulsion is removed. Mu will depend on the approach to the parents. Official sponsored health education has already had conside able success with immunisation against diphtheria but the case for vaccinating infants against small pox, though a good one, will be harder to prese attractively through the poster, the press, and th cinema. Probably the family doctor will have to d most of the persuasion.

The chief bugbears of vaccination are the bad ar and postvaccinal encephalomyelitis. The latter, rare complication, seems very rare indeed whe primary vaccination is not performed at school ag or during adolescence—a fact which forms a su stantial though somewhat awkward argument i favour of vaccination during infancy. The bad ar is a different and in some ways more importa matter. A severe local reaction, with or without mild general reaction, is fairly common, especiall in adults, and though its consequences are rarel serious it can cause a good deal of pain and tem porary disability. Much parental opposition t infant vaccination probably comes from a perso experience of this sort, perhaps after joining th Forces.

There is some reason to believe that the techniqu of vaccination can influence the incidence and severit of local reactions. In this country a single insertio through a scratch not more than a quarter of an inc long, has been recommended[1] to public vaccinato since 1930 for ordinary civilian vaccination; and th Service departments have mostly followed su In the United States another method known "multiple pressure" has been officially recom mended[2] for over twenty years. In this method th skin over an area about an eighth of an inch in diamete is subjected merely to a number of "pressures" wi a horizontally held needle, and there is no scratc nor even pricking of the skin as in another metho described by PEIRCE[3] in 1937. Intracutaneous o subcutaneous injection of ordinary vaccine lymp has never been advocated, but these methods o insertion have been tried with bacteria-free suspension of vaccinia virus obtained by egg culture and othe means. When HENDERSON and MCCLEAN[4] inoculate a suspension of the elementary bodies of vaccini

37 80% of the sweet corn for canning was grown hybrid seed.

Maize is a diœcious plant—that is, it produces male and nale flowers on the same plant. The male flowers, "tassels," at the top of the plant shed their pollen the slightest wind on to the stigmas or "silks" of e female flowers lower down. By growing two inbred re lines side by side and removing the "tassels" m one variety as soon as they appear, the fertilisation the cobs with pollen from the other variety is assured, d a "single-cross" hybrid, with the characteristic brid vigour, is obtained. If seed from self-fertilisation such a hybrid is grown, the next generation shows gregation and loss of the hybrid vigour. To maintain e vigour and uniformity of the cross, new hybrid ed must be produced in the same way every year—costly process and one which can only be undertaken on large scale by commercial seed-growers. Nevertheless, pays the grower to purchase this seed rather than to ow the ordinary varieties. Other types of hybrid an the "single-cross" are now sometimes used, because ey can be produced more economically, without loss the hybrid vigour. Thus, "top-cross" hybrids rosses between an inbred line and an ordinary variety), double-crosses" (two different single-crosses hybridised), d "three-way crosses" (with the seed parent a single-oss and the pollen parent a third inbred line) are now regular production. If only more of our food plants ere diœcious, their cultivation might, with heterosis, e revolutionised in the same way as the American corn-owing industry.

ENICILLIN AND SULPHATHIAZOLE IN TYPHOID FEVER

SINCE Bigger's report[1] on the apparently synergic tion of penicillin and sulphathiazole on strains of *acterium typhosum* in the test-tube, clinicians have been terested in the possibility of using this combined emotherapy against an infection which regularly takes s toll of 10 to 20 patients in every 100 cases. As igger showed, penicillin in a concentration of 2 units r c.cm. in vitro has an inhibitory but not bactericidal tion on some strains of the typhoid bacillus, and when is level of penicillin is combined with 10 mg. of sulphahiazole per 100 c.cm., most strains of *Bact. typhosum* re killed or effectively inhibited. With the recomended dosage of 2 mega units a day for the treatment typhoid cases a level of 2 units per c.cm. of penicillin the blood can usually be surpassed although levels of mg. of sulphathiazole per c cm. are rarely obtained ith the usual dosage of 6–8 g. per day. However, *act. typhosum* in moderate numbers can be inhibited vitro by lower concentrations of sulphathiazole –5 mg. per 100 c.cm) so that the combined therapy ould theoretically be effective. As a rule the best results ith chemotherapy are obtained in the early stages of an fection, when the pathogen is actually multiplying in e tissues, and on this basis the penicillin-sulphathiazole eatment of typhoid should be most successful before e end of the first week when the organism is still resumably proliferating in such foci as lymphoid tissue, one-marrow, and the gall-bladder. Less striking sults would be expected with treatment begun after e end of the second week, when typhoid toxæmia and lceration of the bowel with its attendant risks f hæmorrhage and perforation are the main features of e disease. Unfortunately few cases of typhoid fever re diagnosed in the first week of infection but penicillinlphathiazole may be exhibited in the early stages f the not infrequent relapses, while McSweeney[2] has laimed good results in a few cases treated in the second nd third weeks.

When treatment is begun late useful objective criteria of the severity of the disease may be a positive blood-culture and low titre of O antibody. Blood should therefore be taken immediately before treatment is begun; the clot is cultured in bile or bile-broth and the serum examined for agglutinins. Besides its effect on the clinical infection careful observations should be made to find whether penicillin-sulphathiazole therapy will eliminate the infecting organism and thus secure early bacteriological cure. After an attack of typhoid fever, patients may continue to excrete the organism for many weeks in convalescence and it is estimated that some 2% of affected patients become chronic typhoid carriers. In the convalescent stage the organism persists mainly in the gall-bladder and bone-marrow; in the chronic carrier the usual focus is the gall-bladder, although, as the recent Aberystwyth outbreak exemplified, the possibility of urinary carriage must not be forgotten. Penicillin is concentrated in the bile as well as in urine and with massive doses effective levels may be obtained. McSweeney reported early negative fæcal cultures in 3 of his 5 treated cases (he does not say whether selective culture media were used) and in this issue (p. 343) Comerford, Richmond, and Kay record apparent success in the treatment of 2 typhoid carriers. In the past medical treatment of the chronic typhoid carrier has been uniformly disappointing, though cures have lately been claimed in individual cases with sulphaguanidine and succinyl sulphathiazole. In some of these cases chemotherapy has followed apparent failure of cholecystectomy —as happened with one of the 2 carriers now reported—and it is only fair to point out that cholecystectomy rarely leads to bacteriological cure before several weeks and occasionally months have elapsed after operation. Because of the possibility of intermittency of excretion it is wise also to continue laboratory examinations of fæces and blood (for Vi antibody) for at least a year after apparent cure. However, the results reported by Comerford and his colleagues will encourage others to try the effect of penicillin-sulphathiazole in chronic typhoid carriers, many of whom are known and kept under supervision.

A complicating factor that deserves attention when large doses of penicillin are being used for the elimination of relatively resistant organisms is that commercial preparations may contain 3 or 4 different penicillins[3] the activity of which vary in vitro and in vivo against different bacteria. Thus penicillin III (X) has been shown[4] to be more active than penicillin II (G) against pneumococci, hæmolytic streptococci, *Bact. coli*, and possibly gonococci, although in the usual standardisation tests the two penicillins are equally active against *Staph. aureus*. American workers[5] have also found that penicillin IV (K) although highly active in vitro against *Staph. aureus* and also against *Treponema pallidum* is relatively ineffective in the treatment of experimental rabbit syphilis, a phenomenon that has been correlated with its rapid disappearance from the blood. The poor results, compared with early successes, that have lately been reported[6] in the penicillin treatment of syphilis are also blamed on the high content of penicillin IV in commercial penicillin. Whether the increasing use of *Penicillium chrysogenum* and the deep tank aeration methods of production favour a greater yield of this biologically inert penicillin are matters for further investigation. Meanwhile these disturbing findings may largely invalidate the internationally accepted method of penicillin standardisation, the full report[7] on which was lately published as a special *Bulletin* of the Health Organisation. Obviously the manufacturer must take

the workers, but for comparatively well-to-do families. Further, just before the outbreak of the late war at least 225,000 houses were needed to complete outstanding slum-clearance schemes, quite apart from the vastly greater number of substandard houses which were sliding into slumhood in 1939. Nearly 300,000 houses were required to deal with overcrowding schemes at the exceedingly low standard set up for this purpose. About 150,000 houses were damaged beyond repair by enemy action. At least another 300,000 are needed to provide for the increase in the number of families since 1939. Miss MARIAN BOWLEY, PH.D.,[1] whose illuminating researches have produced a wealth of figures on the housing situation, estimates in addition that nearly four million workers' houses built before the 1914–18 war are so far below the lean standard of the three-bedroom, non-parlour house built by local authorities between the wars that they require replacement.

All the available evidence points to the conclusion that there is a great dearth of three-bedroom houses within the income range of working people, but this does not of itself prove that three-bedroom homes are desirable for the majority of families. We are confronted here with questions of opinion. In the Housing Manual of 1944 the Ministry of Health recommend the provision of three bedrooms of the following dimensions: first, 135–150 sq. ft.; second, 110–120; and third, 70–80. It is true that the young married couple do not require two and a half bedrooms until they have a child; but it is good for them to be able to contemplate the possibility of having a child without worrying about the accommodation, even for the confinement. People who are aghast at the thought of three bedrooms for working folk seem to have no idea how small the space really is, or what a blessing the little third room is for a variety of domestic purposes. They forget that such families may want visitors; that, like the rest of us, they often have to provide for aged relatives; and that there is sometimes sickness in the family. If we really mean to pursue a population policy, we ought to encourage families to have children. It is mere humbug to pretend that they will get larger houses when they have three children. In matters of this kind the stimulus should come before the event, and not as a lollipop promised for good conduct. In building houses to last sixty years we have no right to assume that the downward trend in family size will continue; even if it were to do so, the present area of a three-bedroomed house is nothing to be alarmed about—800–900 sq. ft.! As MUMFORD[2] says: "It is a false solution to build a dwelling so small that the psychological harmony of family life is sacrificed to economy of space."

Subscribers who have not already indicated their desire to receive indexes regularly as published should do so now.

Annotations

AN INTERNATIONAL GATHERING

THIS year's conferences, after the lapse since 193[illegible] have all the savour of long-deferred family reunions. The international meeting under the chairmanship of Sir Hugh Lett, which, as announced in our news columns, is to be held towards the end of this month in London, will be attended with peculiar zest; for it is to be a world-wide gathering. Invitations have been sent to organisations in 42 nations, and the majority have already accepted. The principal business will be consideration of means to promote international liaison in medicine. This has hitherto been the aim of the Association Professionnelle Internationale des Médecins; but the A.P.I.M. has been concerned solely with professional and social medicine. The time has come for a wider range of international coöperation.

It is especially to be hoped that the new organisation foreshadowed in the agenda will sponsor an improved exchange of information, particularly on medical research. Rumour has it that several of the world's leading nuclear physicists are actively discouraging young men of promise from pursuing their specialty because they believe that the free exchange of information essential to progress in this field will never be resumed. No similar embargo threatens medicine; but some of its branches are rapidly becoming almost equally complex, demanding, no less than nuclear physics, the benefit of world-wide consultation. It is true that the main course of research in other countries is known to most in the top flight of their specialties; it is true also that the results of research are more or less easily available to all countries, through the medium of the *Quarterly Cumulative Index Medicus*, published in the United States. But to announce results is not enough: the time for the sharing of information is before research is initiated. Many forms of investigation must be planned and integrated globally if overlapping and needless reduplication are to be reduced and if each country's facilities and aptitudes are to be used to the best advantage.

HYBRID VIGOUR IN SWEET CORN

IN Britain the word "corn" denotes all kinds of cereal grains, whereas in America it refers exclusively to Indian corn or maize. This often caused confusion with our American friends during the war. Most people in this country understand, however, what is meant by the term "sweet corn"—the type of *Zea mays* characterised by a higher sugar content than the "field" corn used for animal feeding. Before 1939 sweet corn was not widely grown in this country, owing partly to unfamiliarity with methods of preparation and partly to the uncertainty of yield in our capricious climate; but interest was stimulated by the influx of American soldiers during the war and the call for vegetables to replace those normally imported. In the subsequent search for early varieties that might ripen successfully in this country, interest centred on the "hybrid" corns.

To most people a hybrid is a cross between two unlike parents, whether of different species or of different varieties; but with maize it has come to have the restricted connotation of a controlled cross between two or more inbred "pure lines," each with definite characteristics. Prof. George Shull, of Princeton University, was the first to show that by the crossing of two pure lines, each of which might be of very low yield, a hybrid of much greater vigour than either parent could be produced; he introduced the word "heterosis" to define this phenomenon of hybrid vigour. He began work as long ago as 1905, and by 1914 he had formulated all the principles for the commercial production of hybrid corns; it was not until 1924 that these valuable types began to be used in the United States, but by

This poses a triple problem: first, the relationship ween sterility and tuberculous endometritis; secondly, situation of the original tuberculous focus, which y, or may not, have been genital; and thirdly, the nificance and prognosis of the uterine disease. In a evious article[6] Halbrecht outlined the past history 18 cases of tuberculous endometritis; of these, 2 had d pleurisy in youth, 2 had had tuberculous peritonitis, d 3 others showed signs of other tuberculous affections persistent pararectal fistula, tuberculous adenitis, or p disease. It therefore appears that the endometrium ovides a long-term sanctuary for the tubercle bacillus. the same way that the gall-bladder harbours the phoid bacillus. The sequence is probably this: primary cus in lung or abdominal glands, systemic tuberculosis dissemination to the pelvic peritoneum, exosalpingitis endosalpingitis with tubal occlusion, and finally sidual tuberculous endometritis.

In a final word of reassurance, Halbrecht says that part from the endometritis his patients were all fit by ternal standards, and that, except for obliterating e tubes, the disease remained stationary and untrouble- me. For treatment he advises absolute conservatism ith complete abstention from surgical intervention. is conclusion that occult, subclinical tuberculous endo- etritis is one of the cardinal causes of sterility in general nd of tubal occlusion in particular may have come as omething of a shock to English workers; and it will e interesting to see whether, with further experience, milar reports appear in this country.

BOVINE PLASMA AGAIN

DURING the war there were several reports[7,8] on the se of bovine plasma or serum, and bovine albumin, blood-volume-restoring agents in man; but none of e authors felt justified in proposing their unrestricted se.

Any protein-containing substitute for human plasma ust obviously be non-antigenic, non-toxic, and free om agglutinins, and it should have at least the same motic pressure as human citrated plasma. None of the orkers who have reported so far have been willing to ate unequivocally that the first condition has been lfilled, while the solutions of highly purified ox-albumin epared in Cohn's laboratory at Harvard and used by eyl et al.[8] alone appear to fulfil the second. Of the vine material used, the ox-albumin seems least open criticism, and publication of the final conclusions awn from its trials—if in fact trials have been continued —will be very valuable. Meanwhile a report from arcelona on the preparation of bovine plasma and its se in man is published on another page of this issue. r. Massons has subjected his material to rigorous treat- ent to make it sterile and non-antigenic, but before e adoption of his bovine plasma can be recommended is claims must be substantiated by careful repetition his work, followed by controlled clinical trial. It is likely that the osmotic pressure of Massons' material equivalent to that of human plasma; indeed it is robably much less. His method of preparation is mple compared with Cohn's elaborate and expensive actionation, but its extreme simplicity will itself voke criticism.

The chief advantages of using a substitute for human lasma are that it will remove the danger of transmitting epatitis, and will lighten the burden of the many blood- onors who have given so faithfully. Unfortunately much ork still remains to be done before this can happen. o protein-containing substitute for human plasma n be employed until it has been clearly shown to be ot only harmless but also as effective as human plasma.

CURARE IN NEUROLOGY

APART from anæsthesia, there are two outstanding uses for curare in medicine which may deserve more attention. There is mounting evidence that it can be used with reasonable safety by intravenous injection to minimise the chances of fracture in convulsion therapy, especially in the elderly. Palmer[1] has summarised the technique required. What may finally prove to be a much wider field is in spastic or dystonic neurological conditions, where no radical treatment is possible, and spasm limits the value of all forms of physiotherapy. Results have been published, for example, in tetanus, status epilepticus, infantile spastic paralysis of several kinds, parkinsonism, paralysis agitans, and Huntington's chorea. They have been dubious so far, for two reasons. There have invariably been troublesome side effects—blurred vision, diplopia, general weakness, and dizziness—and the effect has been transient, and not sufficiently definite in proportion to the severity of the symptoms to justify its routine use. Schlesinger[2] has now introduced a new factor by injecting the curare intramuscularly in a mixture of peanut oil and white wax, and so obtaining slow absorption. He finds that its action is thus prolonged up to three days, and that the unpleasant side effects do not develop. Confirmation is required, but it may be that this modification in technique will lead to welcome, although probably partial, relief for many patients who at present live many months functionally helpless. It should not be forgotten that a number of drugs, such as quinine methochloride, magnesium sulphate, and erythrine, are believed to have pharmacological effects similar to curare. There might be an advantage in achieving the same end with some such physiological analogue.

FOR AULD LANG SYNE

THERE can be few who served in the Forces during the war years who do not find some pleasure in the recollection. Perhaps memory is happily selective; perhaps, again, the rigours of present-day civilian life lend fictitious charm to any alternative. Whatever the reason, the tedium, the irritations, the occasional danger, and the frustration that largely compounded the life of the amateur soldier usually defer to happier memories. The life, though physically dangerous, was otherwise secure, with food and pay assured without special endeavour; many had the chance to see countries they would otherwise never have visited; and the return to the schoolboy community way of living fostered friendships which, but for the common share of discomfort and danger, would never have been sealed. The value attached to these ties has been shown by letters in our columns in the last few months: for the Army, a medical society has been proposed, and an airborne medical society is being formed. Mr. T. J. Daly, a former major and quartermaster, R.A.M.C., now writes to suggest an Army medical association to hold reunion dinners throughout the country; he offers fuller particulars of a tentative scheme to anyone writing to 1, Lancashire Road, Bishopston, Bristol. Ideas of this sort will be warmly supported by those who seek to preserve the little good that has emerged from the lost years.

SYSTEMATIC research into the common cold is to be undertaken in the United States, as well as in Great Britain (see *Lancet*, 1946, i, 822). In America, the investigation will be made by the National Institute of Health (the research division of the United States Public Health Service), directed by Dr. R. E. Dyer. Like the British workers, Dr. Dyer emphasises that it may be five or more years before substantial progress can be recorded, even allowing for the better understanding of viruses in the last decade.

steps to avoid producing penicillin with a high content of penicillin IV or alternatively must use methods for its elimination from the finished product. Failing the production of specific penicillins such as II or III, it would also seem desirable to supplement the in-vitro tests for penicillin standardisation by methods that have more direct relationship to therapeutic efficiency—e.g., the determination of residual penicillin levels in the blood of suitable animals.

DEATH AFTER SERUM

A DOMESTIC tragedy in Ireland, lately reported in the daily press, underlines the possible dangers of antitoxin, which were discussed in these columns a few months ago.[1] Having good reason to believe that one member of a household had contracted diphtheria, a doctor decided to protect the seven contacts by giving each a dose of antitoxin. The last to receive the injection, a girl of 14, complained a few minutes later that she had had an attack of asthma. Administration of a cardiac stimulant was of no avail, and the child died with acute heart-failure soon afterwards. The extreme rarity of such occurrences —perhaps 1 in 80,000 injections—is no reason for underrating their seriousness. Children are more liable than adults; crude serum is more likely than refined antitoxin to cause disaster; no intradermal or other test of sensitivity is entirely reliable; a history of asthma is a warning of the gravest significance; a bottle of adrenaline should be at hand, ready for immediate use, whenever an injection of serum is given. Such in brief is the extent of our knowledge. The induction of passive immunity, perhaps combined with active immunisation as suggested by Fulton and his colleagues,[2] is not only justifiable but also highly desirable on many occasions, but it must never be forgotten that it carries a small but definite risk.

A SCHOOL FOR DIPLEGICS

FEW conditions give such a false impression to the onlooker as cerebral palsy. A child moving with great difficulty, his knees rubbing together or crossing, his arms bent stiffly on his breast or sweeping about in athetosis, his lips dribbling, makes a picture which to the inexperienced means idiocy. Yet many such children are normal mentally, two-thirds of them are educable, and even those who reach colonies for mental defectives are usually among the higher grades. They may achieve much success in managing their disabilities, sometimes with little training or encouragement; it is remarkable to see how a boy learning weaving, for example, will wait for the exact moment when his athetosis will allow him to throw the shuttle. In the United States, where there are said to be some 200,000 cases, considerable advances have been made by Dr. Phelps, of Baltimore, among others, in the training and education of children with cerebral palsy. Now, thanks to the generosity and enthusiasm of Mr. Leslie Williams, who has subscribed a large sum of money and given much of his time to fostering the scheme, and of Colonel and Mrs. Garwood, who have lent their house at Croydon rent-free for seven years and contributed to the fund, a school for British children with this disability is to be founded.

At a luncheon to launch the scheme, held at the Trocadero Restaurant on August 26, Dr. Earl Carlson,[3] himself a diplegic, spoke of the school he has established in New York for 75 palsied children, aged from 2 years upwards. Of his staff of 30, 5 are trained teachers, and others are being trained for this work. Calling cerebral palsy the most neglected condition of childhood, he described the case of a young man who at 20 could not read and could scarcely talk; after 10 years of proper teaching he was admitted to a university and took a PH.D. He is now head of the high-school department Dr. Carlson's school. Children attending the scho for mental and physical training usually need stay o a few months. Dr. Carlson can estimate their intel gence; he finds, whatever their physical state, and c judge whether any child over the age of 3 years educable. Some return to the school for a few m at the age of 18 years before going on to a univers St. Margaret's, the new school at Croydon, will begin a small scale, but this short-stay plan will make it possi to deal with relatively large numbers of children. At f preference will be given to children who can feed the selves, are not incontinent or mentally defective, a who show a good promise of improvement.

The incidence of cerebral palsy is unknown—one es mate is 5–6 per 100,000 population. The cause is st doubtful, for though the theory of birth-injury long h the field (and the mothers often give a history of diffic labour), the pathological findings suggest rather a bl falling on the brain earlier in fœtal life, destroying s developing cells and allowing others, perhaps n mature, to escape; in the light of recent work infecti dietetic factors will no doubt be inquired into. Wheth the case is predominantly spastic, athetoid, or atax depends on the sites of the damage. The Rh fac probably has some part in the ætiology, for half Dr Carlson's patients give a history of jaundice in infancy

The house at Croydon is already being adapted to it new purpose. The board of management consists Mr. Williams, Prof. J. M. Mackintosh, Sir Ernest Cowell and Dr. William Moodie, and the medical advisers to th school will include a neurologist-pædiatrician, an orthopædic surgeon, and a specialist in physical medicine, al of whom will also be on the staff of Queen Mary's L.C.C Hospital for Children at Carshalton. The board a looking for a hostel where the parents of those enter the school can stay for a time to learn how to help the children. Miss Kathleen Wood has been appoint headmistress of the school. Two physiotherapists the staff have completed a three months' course in D Phelps's clinic, and an educational psychologist, out by the Foundation for Educational Research, who h studied the work being done in a large number of th clinics in America, will make St. Margaret's her hea quarters for research and for developments of the mo ment. It is hoped that the school will be in operati by the end of October.[4] The Ministries of Health a Education, the Foundation for Educational Resear the National Council for the Care of Cripples, a Parents' Associations all favour this new developme and it is planned to make St. Margaret's the foremo of similar schools in different parts of the countr giving education and care to such unfortunate childre within the means of all their parents.

TUBERCULOUS ENDOMETRITIS AND STERILITY

THE association between sterility and tuberculo endometritis has been recognised only in the last 4 years, but Halbrecht,[5] in reviewing 820 cases of sterili in women who were subjected to curettage in Tel-Av has found that 45 had tuberculous endometritis. Th diagnosis was confirmed by positive culture in 4 ca and by animal inoculation in 3. Unfortunately, n account is given of the histological criteria for th diagnosis, but he suggests that the number of positi findings would have been greater if all patients had be submitted to a total curettage rather than to a parti or diagnostic endometrial biopsy. As a corollary h investigated 54 women in whom salpingography showe the tubes to be partially or completely blocked; th findings on curettage demonstrated that 18 of these ha tuberculous endometritis.

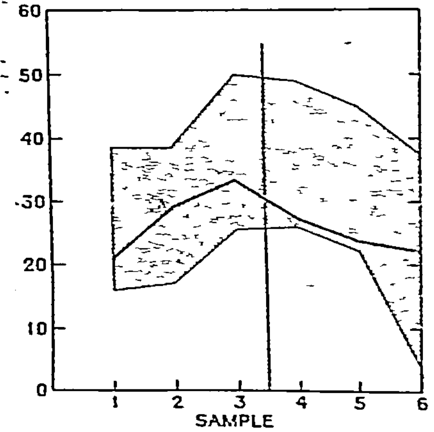
ceptions (Hoelzel 1942), ,many workers support the ea that stress causes reduced secretion and delayed nptying. Wolf and Wolff (1942), in their observations "Tom," and Wolff and Mittelman (1942), in further- servations on cases of gastritis, duodenitis, and peptic cer, distinguish between anxiety associated with stility, resentment, or aggression, which causes hyperfunction of the stomach, and anxiety associated with depression, which causes hypofunction. They note the parallel between gastric secretion and salivary secretion. The mouth dries up with fear, but people spit with rage. Hinds Howell (1941) found that test-meal curves ring air-raids were so irregular as to be useless, but unfor- nately details were not published. Since no unselected mples could be found in the literature, it occurred to ıe of us to do fractional test-meals on students awaiting ıe results of the M.B. examination, to give the results ter the first hour and to follow the curves for a further our to see if passing or failing had any influence. Twenty udents volunteered, of whom sixteen passed and four iled. The technique used was to draw off as much of ıe fasting secretion as possible and then to give a gruel ıeal. All the subjects either went without lunch or had ı early light carbohydrate meal. The tubes were passed etween 4 and 4.30 P.M., samples were removed at)-min. intervals, and the examination results were nounced at 5.15 P.M.



aph showing mean free HCl of 16 students who assed and 4 who failed in their examinations. haded area gives range of mean ±2 S.E. in the 16 who passed; black line gives mean of 4 who failed; ertical line gives time of announcement of xamination results.

The accompanying table and figure show the exact me relationship of the samples to the announcement of ıe results. There is no evidence of hypersecretion and o significant departure from expectation. It might e argued that the tension was not great enough. We o not believe this is valid, as during the first hour there as a definite tense atmosphere in the room, and it was eliberately increased by sending messengers out to ıquire if all the results were yet ready, and by consulting ıeets of foolscap. Possibly a larger sample might pick ut the occasional abnormal case, but evaluation would ıen be difficult.

SUMMARY

Fractional test-meal curves on twenty normal medical udents for an hour preceding and an hour following the eclaration of examination results showed no abnormality hich could be ascribed to anxiety, depression, or lation.

In England Now

A Running Commentary by Peripatetic Correspondents

ONE of your correspondents has urged a more careful estimate of the results of surgery by following up the later histories of patients. Then your leading article of August 17 has drawn attention to the grisly state of some of the chronic sick, as discovered by a survey undertaken by the Institute of Almoners, and among these "chronic sick" were men and women dying of carcinoma in varying degrees of misery. The surgery of carcinoma has to some extent already been checked by follow-up, and judging by the number of forms now filled in about these patients the follow-up will be more accurate and detailed and more widespread than heretofore. I have however an uneasy feeling that the form of the accepted carcinoma follow-up leads to surgery which often adds to the unhappiness of our patients instead of alleviating it.

The accepted criterion of success in the treatment of carcinoma is the survival of the patient for an arbitrary period of years. Whether the patient is happy and comfortable or in misery and pain is not recorded: his mere existence alive is regarded as proof of success. Because "survival" is an unpleasant word, hinting that life may be present but not necessarily very enjoyable, it is not used in this connexion; the fallacious but comforting word "cure" is used in its place. A surgeon will blithely record in public the results of his treatment of carcinomatous patients as a three, four, or five year "cure," lumping together the remainder as "recurrences" and therefore failures. Yet the end of a patient with a recurrence may be a good deal pleasanter than that of a patient "cured." The comfort of the patient has become obscured by the attempt to eradicate a disease, an attempt based on pathology and checked by statistics, both of which ignore the happiness of the sufferer who dies in a different institution from that which treats him at first. The introduction of beds for the chronic sick and dying in the same building where primary treatment is undertaken will go some way to humanising the statistics: till then it might be a good idea to record the results of the treatment of carcinoma as "alive," "with or without recurrence," "comfortable or miserable."

* * *

Almost certainly I qualify by residence and occupation to write as a practitioner in a Medically Overcrowded Area (M.O.A.). There is in London one indubitable M.O.A., the one near Cavendish Square; but in present controversy it does not seem to count, and a substantial park and famous wood separate mine from it. Mine is not what it was. There are many more people to the house and perhaps fewer doctors to the street than there were, but I know of six G.P.s and as many dentists within 200 yards of me—there may be more; houses are not thick on the ground so the proportion must be fairly high; and besides we have been "spoken of," mentioned in the same breath with such hotbeds as Bournemouth.

And that brings me to the point. It is time, I think, that someone in one of these strange places spoke up, for nowhere does experience more belie repute; and repute so readily assumes the voice of authority. The whole country now knows our reputed habits. "Wheresoever the carcass is there shall the vultures be gathered together" puts them in a nutshell. Spying from afar the congregation of the wealthy we buy ourselves into a practice on borrowed thousands and have then no choice but to get our money back by prostituting our science and art. Well may we yearn for a Charter of Liberty to deliver us from this bondage! Well may the country's awakening social conscience move it to arise and cleanse the Augean stable! And if Augean stables have parasites, and parasites have socks, well may they be compelled to pull them up and do a bit of honest work elsewhere!

So much for repute. Now for experience. Twenty-five years ago your present peripatetic—no, the third person is impossible. Once upon a time I, being young, eager, married and offspringing, but slightly mellowed by over four years of war, looked about for somewhere to live. We had sampled the M.O.A. as a living-place and

FRACTIONAL TEST-MEALS ON STUDENTS AWAITING EXAMINATION RESULTS

MICHAEL FLOYER
M.B. Camb., M.R.C.P.

DENYS JENNINGS
B.M. Oxfd, D.M.R.E. Camb.

From the Medical Unit of the London Hospital

THE association between disturbance of the guts and emotional tension has been recognised since the beginnings of literature. Older authors attributed emotional instability to weak guts. The pendulum has now swung over, and gastroduodenal and colonic disorders, both functional and organic, are popularly ascribed either to excessive mental strain or to a temperament badly adjusted to normal strains.

Typical evidence for this change of view is the alleged frequency of gut disorder following mental tension. A good example is Stewart and Winser's (1942) paper on the increase in perforated peptic ulcer during air-raid periods. There are many other lines of evidence, such as the undue frequency of certain temperamental types among ulcer patients (Davies and Wilson 1937), observations on the effect of emotion on quite a large number of patients with gastric fistulæ, ranging from Beaumont (1833) to Wolf and Wolff (1942), observations on experimental animals with fistulæ or with transpa abdominal windows, X-ray observations on experimental animals and on normal and psychotic human subjects and finally test-meal observations on mental patients and on subjects suffering from emotional stress or in which stress is induced under hypnosis. Alvarez (1929) has written a very readable review, and Dunbar (194 gives a modern bibliography.

Various mechanisms for the production of peptic ulcers by emotion have been suggested. The idea that interruption of normal impulses from the brain, or the production of abnormal ones, may be responsible back to Kammerer (1818), who tried to explain the association between brain lesions and gastric ulcers. The theory of hypothalamic stimulation in its modern form was favoured by Stewart and Winser (1942) and severely criticised by Jennings (1942). Selye (19 reaffirmed the claims of his "alarm" reaction of ischæmia followed by dilatation of capillaries and sta *Cannon's (1909) view of stasis and fermentation of* food producing irritation, gastritis, and duodenitis is possibility, and so is the idea of retrograde intestinal movements associated with colonic irritability.

As pointed out by Jennings (1942), the difficulty of the theory of hypothalamic stimulation is that, with rar

F, free HCl; T, total acidity; S, starch; B, bile.

th, preferably representing their national health inistrations." The assembly will meet annually and pecial session and determine its own place of meeting dvance. Among its functions is the authority to pt conventions or agreements by a two-thirds vote; nbers undertake to accept such conventions within teen months or furnish reasons for non-adoption. assembly may also adopt regulations on quarantine uirements and standardisation of nomenclatures, gnostic procedures, and biological and pharmaceutical ducts (including their labelling and advertising); such regulations will come into force at a given date ess specifically rejected by members. These are and important powers, designed to ensure uniformity obviate delay experienced in the past, but they y excite opposition if too much is attempted too ickly.

The executive board is to consist of 18 persons desig- ted by 18 delegates elected by the assembly, holding ice for three years and eligible for re-election. The ard will meet at least twice a year, act as the executive gan of the assembly, and take emergency measures. e director-general, who is nominated by the board d appointed by the assembly, has direct access to vernment departments and nominates his own staff, e conditions of whose appointment are to conform those of other United Nations organisations.

The location of the headquarters is to be decided the assembly, and it seems likely that it will be in rope. Regional committees and offices may be set up. soon as possible the Pan-American Sanitary Bureau to be integrated—whatever that may mean—with the orld Health Organisation, by mutual consent. Annual, idemiological, and other reports are to be made by ember-states to the World Health Organisation. The nstitution, which may be amended by a two-thirds ajority of the assembly, enters into force when 26 embers of the United Nations have become parties to : it is hoped that this number will be reached before une, 1947, when the first assembly is expected to meet.

INTERIM COMMISSION

The Arrangement provides for the immediate establish- ent of an Interim Commission of 18 persons designated y that number of States. Its duties are to convoke he first session of the World Health Assembly within ix months of the constitution coming into force; to rovide, for the agenda of the meeting, proposals on rogrammes and budget, the location of headquarters, egional areas, and staff regulations; to prepare an agree- ent with the United Nations; to take over the functions f the Health Organisation of the League, the Paris ffice, and the Health Division of UNRRA relating to the nternational sanitary conventions; to negotiate with he Pan-American Sanitary Bureau and other inter- ational organisations; to prepare for a revision of the anitary conventions and the lists of causes of death; o establish liaison with the commission on narcotic rugs and other commissions of the Economic and ocial Council; and to consider any urgent health problem rought to its attention by governments. The Interim ommission is to derive its funds from a loan by the nited Nations, and governments may make advances o it against their future contributions to the World ealth Organisation.

The commission[2] met in New York immediately after lection by the International Health Conference and lected Dr. Stampar (Yugoslavia) as chairman and Dr. B. Chisholm, late deputy Minister of Health of Canada, as executive secretary; it also set up committees on administration and finance, epidemiology and quarantine, and relations with other bodies. It is understood that its next meeting, which must be held within four months, will be in Geneva early in November.

Finally, in the protocol, the signatories agreed, as between themselves, to hand over the duties of the Paris Office to the Interim Commission or the World Health Organisation on the entry into force of the protocol; and, if the Paris Office has not been dissolved by mutual consent before Nov. 15, 1949, to denounce at that time the Rome Agreement of 1907, thus finally terminating the Office. The protocol comes into force when 20 governments which were signatories of the Rome Agreement have become parties to it.

We may conclude that the United Nations have made a good start in the field of health and that unification is at least—and at last—in sight. The many tedious hours spent by the delegates in the hot-house atmosphere of New York have not been wasted.

Paratyphoid at Coatbridge

On August 22 a case of enteric fever was admitted to the burgh infectious diseases hospital, Coatbridge, Lanarkshire. Next day 3 more cases were admitted. All were bacteriologically confirmed as paratyphoid B fever. All had consumed ice-cream from a common source. On August 24 the manufacture and the sale of the ice-cream was stopped, and local practitioners were informed of the outbreak. A bacteriological investigation revealed that an employee who made and sold the ice-cream was excreting *Bact. paratyphosum B* in his stools. It was not possible to determine the total quantity of ice-cream likely to have been infected, but it is estimated that at least 1500 cones and wafers were sold on one day. The ice-cream was hawked within a certain area of the town, and the cases are confined to that area. The total number of cases up to August 30 was 74, the majority being in children.

Infectious Disease in England and Wales

WEEK ENDED AUGUST 24

Notifications.—Smallpox, 0; scarlet fever, 665; whooping-cough, 2058; diphtheria, 285; paratyphoid, 66; typhoid, 36; measles (excluding rubella), 2140; pneumonia (primary or influenzal), 299; cerebrospinal fever, 39; poliomyelitis, 30; polio-encephalitis, 1; encephalitis lethargica, 2; dysentery, 52; puerperal pyrexia, 138; ophthalmia neonatorum, 82. No case of cholera, plague, or typhus was notified during the week.

Deaths.—In 126 great towns there were no deaths from scarlet fever, 1 (0) from enteric fever, 2 (0) from measles, 8 (0) from whooping-cough, 3 (0) from diphtheria, 29 (2) from diarrhœa and enteritis under two years, and 7 (2) from influenza. The figures in parentheses are those for London itself.

Birmingham reported the death from an enteric fever.

The number of stillbirths notified during the week was 242 (corresponding to a rate of 28 per thousand total births), including 30 in London.

"... There was another occasion during the [Hot Springs] Conference when the delegates of the other nations appeared to be deeply impressed by the clear indication of the trend of thought on food and nutrition in Great Britain. It was when an account was given of the war-time food policy we have implemented here and of the various measures we have adopted to distribute foods according to nutritional needs. After this meeting Professor André Mayer, the distinguished French physiologist, took me by the arm as we walked along one of the long corridors and said in his characteristically charming manner, 'M. Drummond, Vous Anglais, vous faites toujours les révolutions avec tant d'élégance!' "—SIR JACK DRUMMOND, F.R.S., speaking at the Royal Institution on June 2.

---

[2] Mr. Tange (Australia), Dr. Paula Souza (Brazil), Dr. Routley (Canada), Dr. Sze (China), Dr. Shousha Pasha (Egypt), Dr. Leclainche (France), Dr. Lakshmanan (India), Dr. Togba (Liberia), Dr. Mondragon (Mexico), Dr. van den Berg (Netherlands), Dr. Sandberg (Norway), Dr. Paz Soldan (Peru), Dr. Medved (Ukrainian Soviet Socialist Republic), Dr. Krotkov (Union of Soviet Socialist Republics), Dr. Melville Mackenzie (United Kingdom), Dr. Parran (United States of America), Dr. Guzman (Venezuela), Dr. Stampar (Yugoslavia).

liked it. It was a fit place for bringing up a family, not too far from our own parents and from my hospital job, and there was a house going reasonably cheap. There were shoals of doctors about, so one more could matter little to them; and just possibly I should make a living.

We bought the house. We let the top half to friends and I put a plate on the door. I never sat there like a hungry spider twitching the threads of the web. I went out and did jobs—paid and unpaid, hospital, welfare-centre, pensions-board, and the like—and slowly friendly doctors put me in the way of making a practice. Some of the friendly ones were consultants a few years my senior living in or near the M.O.A. and needing a "real doctor" for their children; others were "real doctors" themselves, living farther off. The patients were almost always immigrants—almost never from that day to this the ex-patients of a local fellow-vulture. They were very often interesting and pleasant people, very seldom rich.

The fellow-vultures, after surveying the new bird for a suitable time, actually invited it to join the Vulturine Society—a very friendly gesture when you think what predatory brutes they must really be. "The Vulturine" meets monthly in the winter season in the actual eyries of its members. The eyries turn out to be quite ordinary nests, the hen-vultures who receive us seem quiet, domesticated fowls enough; and where are the tell-tale fragments of bone, fur, or feather that should reveal to a quick eye the horrid hidden sources of their daily meat? How inconspicuous are our host's beak and talons! One might almost believe that even he—and if one almost did one would be right because of course (to quit fooling) neither he nor the other members of the "Vulturine" are any more predatory than I am myself. They are decent ordinary practising doctors, not perhaps without certain qualities of mind and outlook which have drawn them to practise in the M.O.A., but quite obviously neither parasites, charlatans, go-getters, nor prostitutors of their art and science.

* * *

When I die I shall leave an annual prize to the graduate who can give the most bizarre reason for taking up medicine. I might have been a pretty good starter myself. The week before I began at college I filled in a curriculum form for some distance before I discovered that it wasn't the one for arts after all. Somewhere in the college files there is a curriculum form for medicine (1939–40) with a teeny tear at one edge to show how far I got before it struck me that it might be a better stunt after all; whereafter I went straight to a second-hand book shop and bought a textbook of pathology by Lazarus-Barlow (1902 edition) for 1s. 6d. and read it!

The closest rival in my year would be the anatomy medallist, who, during his school years, saw a woman have hysterics in the street when a forearm and head were thrown at her from the upper floors of the medical school. This incident greatly impressed on him the power of the healers over the laity and fired him with the ambition to emulate this feat. Runner-up would be the old sea captain who had been left a substantial legacy on condition that he embarked on the study of medicine. Since the legacy was to stop when he qualified, the old boy spun out his course to 14 years until he accidentally gave three right answers running in his finals and was passed. By the time he had decided to get himself struck off the Register to be able to start again, he found himself enjoying a country practice so much that he bought it with the savings from his legacy instead.

Lest any of you should be tempted to overwork your imaginations, I might add that I am still in my twenties and that the prize, in any case, will be quite worthless.

* * *

"Typhoid Outbreak in Scotland: An Ice-cream 'Carrier'?" says the *Manchester Guardian*. If an ice-cream carrier is a person who harbours ice-cream in his body without manifest symptoms (as Dorland's *Dictionary* would lead one to suppose) most of the children in our part of London must come in that category just now, for the Strand is only second to Southend-on-Sea in the number of ice-cream sellers per sq. inch.

Public Health

THE WORLD HEALTH ORGANISATION AND ITS INTERIM COMMISSION

NEVILLE M. GOODMAN
M.D. Camb., D.P.H.
DIRECTOR OF HEALTH, EUROPEAN REGIONAL OFFICE, UNRRA

THE work of the International Health Conference in New York[1] can now be reviewed in the light of the documents signed at its conclusion. These documents consist of (1) the constitution of the World Health Organisation, (2) an Arrangement establishing an interim commission, (3) a protocol concerning the International Office of Public Health, Paris, and (4) the final act of the conference. All four were signed by almost all the representatives of the 51 member-states of the United Nations and the 10 non-member representatives attending as observers; but the first and third were in most cases signed subject to ratification.

CONSTITUTION

The constitution, after an impressive preamble, defines the objective of the World Health Organisation as "the attainment by all peoples of the highest possible level of health." The first of the organisation's functions is to "act as the directing and coördinating authority on international health work." Among the twenty-one other functions are strengthening health services; furnishing necessary aid in emergencies; providing health services to special groups, such as trust territories; establishing epidemiological and statistical services; proposing conventions and regulations; promoting maternal and child health, mental health, research, technical training, and health propaganda; adopting international standards for biological, pharmaceutical, and food products, and for diagnostic procedures, public health practices, the nomenclature of diseases, and causes of death; and promoting the improvement of nutrition and environmental hygiene. Services will be rendered *only at the request* of governments, and coöperation with other agencies in the various fields is enjoined. The scope is thus even wider than that of the Health Organisation of the League of Nations, the Paris Office, and the Health Division of UNRRA combined, though obviously all these functions will not be taken up from the beginning. Already alarm has been expressed at the proposal to standardise diagnostic procedures, but it seems that all that is intended is the standardisation of laboratory techniques, such as that of the serodiagnosis of syphilis, formerly pursued by the League of Nations.

Membership is open to all States. A simple majority vote of the World Health Assembly will admit any State not accepting membership by signing the constitution as a member or observer at the International World Conference (Spain, Germany, and Japan were the only States not invited to the conference). Colonies or other territories not responsible for their international relations may become associate members on application by the "mother" country; their representatives "should be chosen from the native population"—a clause which may lead to embarrassment—and their rights and obligations will be determined later.

DIVISION OF DUTIES

The work will be carried out by the World Health Assembly, an executive board, and a secretariat. Member-states will be represented in the assembly by not more than three delegates, with alternates and advisers; delegates "should be chosen from among persons most qualified by their technical competence in the field of

tord.

THE SISTER-TECHNICIAN

R,—With regard to the article on Democratic Nursing ıe issue of July 6, we feel it very necessary to protest ngly against one of Mr. Cohen's suggestions. This ıat married sisters working in health centres should e a short training in the duties of a laboratory nician. If sisters trained in this way are responsible the routine investigations the standard of the ratories in the health centres will not be a high one, the work of a technician is highly specialised and is y acquired by many years of experience. In the ıion of this committee, the laboratories should be fed with trained technicians to obtain a satisfactory ıdard of work.

PHYLLIS LANGAN PLUMBRIDGE
Secretary of the Committee.

ondon General Medical Branch, Association
of Scientific Workers.

VARIATION IN THE FEMALE PELVIS

SIR,—In connexion with the article by Dr. C. Nicholson d Mr. H. Sandeman Allen (August 10), I should like to nment on a few variations in the female pelvis which observed in the X-ray department of Shrodells spital, Watford. The patients here are probably presentative of the London suburban population and long to all social strata, being referred for pelvimetric alysis by private practitioners, obstetric specialists, tenatal clinics, and maternity homes in the neighbourod.

A striking feature is the comparative rarity of the pical android pelvis, as described by Caldwell and oloy, with all its associated features—the acute ıgle of the forepelvis, the short anterior transverse ameter, the long and narrow sacro-sciatic notch, the ort posterior sagittal diameter, the deep symphysis ıbis, the narrow subpubic angle, the wide and straight rum, and the deep true pelvis. The incidence of pelves owing at least a few of these characteristics was not re than 6–7% of the total of 1200 pelves examined. In ollow-up of the subsequent course of delivery we found surprisingly high need for interference and assistance this type. While the total need for interference in all ses delivered at home by practitioners and in nursing mes or hospitals was around 11%, the pelves with droid tendencies required assistance in 62%.

To determine an android hind-pelvis we use a much wer figure for the sagittal index than that given by icholson and Allen for their scutiform type. We do t consider the arbitrary figure of 30 for the upper vel of the index as really indicative of a short postgittal diameter if the index for the whole series of 7 cases is not higher than 35·6. The figure which we ipulate as the upper level for the index denoting a ırrow android hind-pelvis is 25. We feel that the clusion of pelves with indices above this figure would ad to very slight variations of the round type being nsidered among the android group. This would lead erroneous conclusions if an assessment of the course labour in relation to pelvic type is attempted.

Table VI of Nicholson and Allen, which gives the athematical basis for their conclusion that pelvic type as no influence on the course of labour, shows however -be it statistically significant or not—that the scutiform elvis required assistance in 46·5% of all pelves of this pe, while the narrow (anthropoid) only required interrence in 32·3%, the flat in 37·5%, and the round in 3·7% in all cases of their respective types. I am connced that if a lower sagittal index were applied to parate the scutiform group from the rest, and thus d near-gynæcoid pelves be excluded, then the percentage sistance rate in the first group would rise considerably.

The correlation coefficient between the sagittal index and the ischial spine distance is very near the limit of being statistically significant and would suggest that with a low sagittal index occasionally an interspinous narrowing could be expected, as is actually the case in the funnelling of the true android type.

I do not think that any decisive conclusions can be derived from consideration of the course of delivery in about 30 cases of the scutiform type. This type embodies only one feature of the android pelvis, and the quantitative limits for inclusion in this type are drawn too widely. From a radiological point of view I do not feel it justifiable to diagnose an android pelvis from the comparative relationship of two segments of one longitudinal diameter in the inlet plane alone, as was done in the case of the scutiform pelvis. I firmly believe that consideration of all the other characteristics at different levels of the pelvic cavity is at least as important, if not more so, and enables one to arrive at a usable prediction about the probable course of labour. If typical android features are present in various parts of the pelvic canal a prolonged and difficult labour is to be expected in the majority of cases in which only the slightest disproportion coexists.

Pinner.

J. RABINOWITCH.

"CURARINE"

SIR,—Some confusion has arisen in the nomenclature of alkaloids from curare which it is important to resolve in view of the renewed interest shown in curarising drugs.

The word curarine was applied by Boehm in 1897 to an amorphous alkaloid which he isolated from gourd (calabash) curare. From tube-curare he isolated a chemically different amorphous alkaloid which he called tubocurarine, and King in 1935 described the isolation and chemical structure of a highly active crystalline alkaloid from tube-curare which he regarded as the crystalline form of Boehm's preparation and applied the name *d*-tubocurarine chloride to it. Dutcher has recently isolated the same *d*-tubocurarine chloride from native curare prepared from *Chondrodendron tomentosum*.

Ranyard West, whose work on the treatment of spastic rigidity, Parkinsonism, and tetanus with curarising drugs in 1932–36 and subsequent years aroused so much interest, worked at first with crude native curares. Later he used an amorphous alkaloid called "curarine" which King prepared from *Strychnos toxifera*, a liane known to be used in the preparation of calabash curare in British Guiana. West ran into the difficulty that cases of bronchospasm often occurred during treatment and has rightly emphasised this danger. Recently, however, reports have been published in this country of nearly 2000 cases of anæsthesia in which a preparation supplied by Messrs. Burroughs Wellcome & Co., as "curarine chloride" has been used without any cases of bronchospasm occurring. The discrepancy between this series and Ranyard West's reports is due to the fact that the drugs used were different; the Wellcome "curarine chloride" is crystalline *d*-tubocurarine chloride derived from tube-curare.

Messrs. Burroughs Wellcome & Co., in naming their preparation "curarine chloride," were actuated by a desire to avoid a polysyllabic name. The term curarine would be better dropped entirely, leaving new alkaloids of this class to carry their appropriate adjectival prefixes, which Messrs. Burroughs Wellcome & Co. now propose to do.

Beckenham, Kent.

J. TREVAN.

AID TO DEFÆCATION

SIR,—Your correspondent, C. W. B. (August 10), advises rubbing the lower back in order to secure an easy defæcation. This is indeed a treatment of value, but it is only successful in suitable cases.

In every great cattle-market you will find wise farmers testing the alimentary canal of a cow or steer they wish to buy by scratching the sacral area of its spine with their walking-stick. This commonly produces an evacuation, and from this excrement the experienced old farmer decides on whether to bid or to abstain.

This method is, however, of less efficacy in the case of horses, and is practically valueless in the case of constipated dogs. The nerve stimulus acting upon the

Letters to the Editor

TREATMENT OF MENINGITIS

SIR,—There is much truth in Dr. Wilfrid Gaisford's remarks (August 17) against intrathecal penicillin and in favour of intensive systemic therapy in "non-traumatic meningitis." But his statement is an over-simplification of the therapeutic problem, since he does not draw any distinction between (1) the various bacterial forms of purulent meningitis, and (2) the different extent of penetration of the blood-brain barrier by serum, sulphonamides, and penicillin in the presence of acute meningitis. Neither of these factors can be ignored in the treatment of meningitis.

Recent pronouncements appear to have given rise to a widespread impression that intrathecal penicillin must at once be given whenever spinal puncture reveals a turbid fluid. "Treatment by penicillin is indicated for all meningococcal cases," we are told.[1] The "introduction at once of intrathecal penicillin if the lumbar tap is turbid" is recommended in addition to sulphonamides and systemic penicillin.[2] Surely the problem has got a *bit out of focus! Is it already forgotten that* prompt and adequate sulphonamide therapy is rapidly curative in about 95% of meningococcal cases? Is there any evidence so far that the cure of these can be hastened by penicillin? I do not think so, nor have I any reason to believe that any considerable part of the other 5% can be saved by penicillin either.

Since the meningococcal form is the most common form of bacterial meningitis, the recommendation for intrathecal penicillin on discovery of a turbid lumbar tap results in much unnecessary intrathecal injection. In the great bulk of such cases doubtless no harm will come of it, but unless the technique is invariably meticulous, which is a practical impossibility, the potential danger is by no means negligible. It is not only that the impurities of penicillin are irritating to the meninges and may even be non-sterile, but the introduction of grave extraneous infection—e.g., *Streptococcus viridans*, coliforms, or *Pseudomonas pyocyanea*—is more common than is generally realised.

In pneumococcal meningitis the balance of evidence at present appears to be in favour of intrathecal and systemic penicillin as well as large doses of sulphonamides. But the evidence for intrathecal penicillin is not so strong as to justify a rush to it without prior examination of a smear from the spinal fluid.

When staphylococcus meningitis is suspected, intensive therapy by all routes may be justified without delay, but this is a rare condition and there is usually some clinical guide to the diagnosis.

It was a great relief, a few years ago, to get rid of the trauma and risks associated with routine intrathecal injections in the treatment of meningitis. Before we return to them let us consider well whether any real *advantage is to be gained.*

London, S.E.13. H. STANLEY BANKS.

SIR,—In his letter of August 17 (p. 253) Dr. Gaisford condemns—in no mild terms—the use of intrathecal injections of penicillin for nontraumatic meningitis. He states that meningitis is a systemic disease and intensive systemic therapy is the best form of treatment. I think most people a short while ago would have been in complete agreement with him; the reason for the "retrograde step in therapy" is surely that patients went downhill steadily and even died when treated on the lines so ably advocated. The observant medical attendants then retraced their steps and tried intrathecal medication, with the result that those patients not beyond recall recovered.

There is a theoretical obstacle to systemic treatment; though not merely banausic it is often referred to as the "blood-brain barrier," and though merely a theoretical obstacle for many of the sulphonamides (as Dr. Gaisford argues with effect) it is a very real handicap when the large molecule of penicillin has to be taken into account.

Epping, Essex. FRANK MARSH.

WATER-SUPPLIES

SIR,—In the *Times* of August 10 I read that Cumberland County Council has been reviewing present and potential supplies of water to the county. Presumably that fortunate county of lakes and [illegible] has water enough available for all time.

But should not some authority at the highest [illegible] be actively inquiring into the available water of [illegible] whole country in view of widespread housing schemes which will entail the provision of large new water-supplies in town and country alike? As regards the country cottagers in village or scattered country districts draw their moderate water-supply from shallow wells (except when these run dry) in quantities limited by habit, by the labour of working buckets and windlass or pump and by what their well may yield at a given time. If all these cottagers and all the new ones promised or to have water by pipe and taps (hot and cold), baths and bathrooms, and water-flushed sanitation, an enormous quantity of new water will be needed. Where is it to be found? Having knowledge of country life, I estimate very roughly that a cottage family at present supplied by a draw-well would, if afforded the "amenities" proposed for baths, w.c.s, and kitchen taps, soon come to use 10, 15, or 20 times the volume of water previously used in daily life. A single lavatory flush runs off [illegible] gallons. The total will amount to very large figures.

I am not enough of a geologist to know whether or where this water can be found, but I read with apprehension from time to time of falling rivers and failing streams whose dwindling flow is attributed to heavy pumping from new deep wells for water undertakings or industry. And it is well known that the water level over the clay of the London basin, for example, has similarly been a good deal lowered in recent years.

Will it not be necessary to take very far-reaching steps to conserve vastly more of the water that falls from the skies, if we wish to use so much more? The question may become one of urgency. Very few of us even conserve the rain that falls on our houses. And from streets, roads, land drainage ditches, and the like we run it off to the sea as fast as we can.

The Cumberland County Council had a comparatively simple problem to deal with: but is it not clear [illegible] we need a general survey of the present and potential water-supplies of the whole country?

Upavon, Wilts. E. W. AINLEY-WALKER.

NON-SPECIFIC EPIDIDYMITIS IN INDUSTRY

SIR,—The recent articles and correspondence on non-specific epididymo-orchitis (*Lancet*, 1946, i, 775, [illegible], 834, 870) raise questions of interest to industrial medicine.

It is not uncommon in my experience to see workmen who develop mild epididymal pain after exertion. The history is usually that, while lifting, pain is experienced over one spermatic cord, and shortly afterwards in the testicle on the same side. As the pain does not quickly settle the workman soon reports to the works' surgery. On examination the epididymis is slightly swollen and tender and there is a tenderness of the vas. In one case the body of the testicle was also slightly enlarged and tender, and in yet another case the symptoms and signs were bilateral. Examination of the urethra and a centrifuged deposit of the urine reveals no abnormality. A supporting bandage usually relieves these patients, the symptoms disappearing in a few days. In [illegible] cases, however, the question of workmen's compensation has arisen, owing to the loss of a few days' working time. In all the cases seen, the symptoms have been mild and the principal anxiety of the patient has been over the possibility of hernia. No signs of this have been discovered.

Apart from these cases, where no obvious urinary infection exists and where the symptoms are mild, I have seen two severe cases of unilateral epididymo-orchitis. These also had, as a precipitating cause, exertion or sudden effort. One had a history of gonorrhœa six months previously, while the other case had flakes in the urine, which contained a fair number of pus cells but no organisms on direct examination.

The questions, both of urinary infection and exertion (given as a precipitating cause), have obvious bearings on these cases in industry. The possibility of bias,

ILDREN WHO SPEND TOO LONG IN BED

—I am not competent to question the accuracy e rules for sleep that Dr. McCluskie lays down in his e of August 31 (p. 302), though I should like to know he obtained his results, and whether he is giving ige or mean figures: from my own very limited cience of infants and children I should have said the individual variation covered a far greater range that of 30 minutes per 24 hours. It would also nteresting to know if a significant proportion of otic children have a history of having been kept too in bed.

particularly want to emphasise the impossibility of wing Dr. McCluskie's rules when there is more than child in the family. It might be feasible, even for unassisted mother, who has cooking, shopping, and sework to do, as well as looking after the baby, to nge her time-table so that an only child could be sed from its bed directly its 12 hours at night and or 2½ in the day were up. But when there are two nore children, one perhaps an infant on four-hourly st-feeds, the difficulty of getting Tommy up after hour's sleep in the afternoon, of keeping John y from 7.0 A.M. to 7.0 P.M. without a break, of ing Mary at 6.0 A.M., 10.0 A.M., 2.0 P.M., 6.0 P.M., and P.M. would send most mothers to the psychiatrist heir own account, before their children were so much threatened with that modern bogyman. Dr. luskie should remember that after the children have put to bed there is still their father's dinner to cook. if that is to be followed by a round of "pottings" a 10.0 P.M. breast feed, can we blame the mother does not rise at 6.0 the next morning to feed infant and wake and dress the children who have n in bed since 6.30 or 7.0 the previous evening? ould also like to know how Dr. McCluskie deals with infant who is not old enough to sit or crawl and who, n propped up in a pram with his toys around him enjoined to stay awake because this is his playtime, ceeds to fall asleep in the most uncomfortable position sible, in spite of having slept 14 hours the previous ht and 3 hours that same morning.

feel strongly on this subject because it seems to me t this is another case of the academic approach being d to a problem that is mainly human and domestic. many overworked women are unnecessarily worried heir babies' meals are 15 minutes early or late, though baby may raise no objections. Don't let us overload ir consciences further by threatening them with urotics or psychopaths for children if they treat themves to a 7 or 8 hour night or an occasional half hour's t in the afternoon. The neurotic mother, however dly she adheres to a time-table, is not likely to bring the happiest or even the healthiest children.

ondon, W.11. CATHERINE STORR.

A SYNDROME SIMULATING ACUTE ABDOMINAL DISEASE

SIR,—The paper by Mr. Goldstone and Dr. Le rquand in your issue of August 24, in which they scribe what they believe to be a new abdominal ndrome occurring in European Servicemen in West rica, was most interesting to me as their description ry closely simulates and indeed may be identical th, a condition which can also occur in West Africans d which I described last year (*J. R. Army med. Cps*, 45, 84, 201).

Briefly, among 230 cases of infective hepatitis in gerian troops seen over a period of two years, there re 7 cases which were so striking clinically, and so sely resembled each other, that I called the group the acute abdominal syndrome" and emphasised that eir importance lies in the fact that a surgeon with no perience of such cases might easily feel it his duty explore the abdomen even in the presence of jaundice.

Could it be that the cases of Mr. Goldstone and Dr. Marquand were in fact suffering from latent or subnical infective hepatitis? Although the urine was sted in each of their cases, in subicteric patients bilelts are present only intermittently in the urine, and veral specimens at intervals should be examined. Or uld it be that my cases were suffering from this new ndrome which presumably came on during the course of infective hepatitis? Whatever the answer the clinical similarity of our cases is striking and the prognosis without surgery excellent. In support of your contributors' theory of a staphylococcal origin, and for what it is worth, staphylococcal infection (pyomyositis) is very prevalent among West Africans.

In over a year's service with native Indian troops in India no similar cases were encountered.

Stoneleigh, Surrey. S. ORAM.

ENTERTAINING ALLOWANCE IN THE NAVY

SIR,—The recent Admiralty Fleet Orders (453–457) set out the entertaining allowance for Executive Officers, Royal Marine Officers, Wren Officers, Engineer Officers, and Supply Officers (Paymaster Branch), but no mention is made of the Medical Branch. For many years the Medical Branch have felt that they have a very justifiable grievance in that senior officers have no entertaining allowance and yet are expected to give hospitality to Admiralty visitors and anyone whom Parliament wishes to be entertained at the hospital. During the war years this was a very heavy item and numerous foreign and allied officers were given hospitality on many occasions. It seems that every branch of the Navy is given entertaining allowance except the Medical Branch, and this surely should be put right.

London, W.1. CECIL P. G. WAKELEY.

ADVERTISING PATENT MEDICINES

SIR,—Dr. Thompson's article of August 24 on the advertising of patent medicines in the public press "provided ammunition" in plenty for those who would attack the more unscrupulous methods adopted by the trade; but he did not touch on an aspect of the subject to which our own profession can give immediate remedy—the trading on the gullibility of doctors in the medical press. An all-wise Government now sees to it that only a limited proportion of the morning mail contains literature from the drug firms; but recollections of the bad old days before the recent war teem with pamphlets, all of them persuasive, most of them expensively got up, some of them well-written, but few of them read and almost none of them asked for.

I am well aware of the purpose and importance of this form of literature, and I neither question the wisdom of the drug firms in spending their money and their highly qualified employees' time on its production, nor the usefulness of some of it to the medical practitioner. Nor do I suggest that any of the medical journals should be without their advertisement section, quite apart from the financial side of the question. But when I look through the advertisements composed for the notice of the medical profession it seems to me that some take a great many high sounding words to say very little; others endeavour to blind the humble doctor with science, or pseudoscience; a few are frankly misleading. On the other side of the coin are all the arguments which could be advanced by the advertisers, many of which are readily admitted. The point, however, is this: that doctors are themselves susceptible to the pressure of advertisements, and to the salesmanship, as opposed to the information therein contained, and are liable to accept the over-simplification (of imperfect scientific knowledge) which is designed to sell a product. They thus contribute to the perversion (and consequent increased cost) of advertising, which is usefully employed in bringing genuine innovations to the notice of the profession, but crosses the frontier between ethics and mercenary expediency when it suggests that the opinion of an anonymous authority, or the testimony of some thousands of medical practitioners, which favours a particular product, however elegant, is a scientific fact.

Camberley, Surrey. W. LANE PETTER.

OUR HOUSES

SIR,—Mr. Saward (August 24) is quite right. Of course every house should have two w.c.s. *and* with hand-washing basins. But when the waterworks company impose an annual tax of 10*s*. on each "extra" w.c., as they do here, people have to put up with minimum essentials. Blame the waterworks, not the general public

Bristol. ARTHUR T. SPOOR.

nerves of the intestinal muscles produces an immediate reaction when the contents of the intestine are comparatively liquid; the nerves of the skeletal muscles, which are called into play in the case of hard fæces, are not affected. Cows therefore readily react, but the habitually constipated human must not expect such a result unless he regularly takes a daily meal of foods like boiled beetroot, grated raw carrot, grated raw turnip, or cabbage.

The same mechanism comes into operation when a hay rake is applied to the sacral spine of a lazy bull; in this way the muscles of the vas deferens are stimulated, but not the skeletal muscles themselves.

London, W.1. JOSIAH OLDFIELD.

SIR,—Your correspondent may be interested to know that this manœuvre was described in my *Treatment of Some Chronic and Incurable Diseases* (Bristol, 1937, p. 106), a second edition of which is in the press:

> "A wave of colon peristalsis can often be encouraged by auto-massage of the muscles just above the left posterior superior iliac spine. With the fingers of the left hand close together, a circular clockwise pressure is made over an area about the size of half a crown, the skin being fixed under the fingers. *This can be practised in the lavatory, if a motion just fails to come.*"

Incidentally this spot is one to which the descending colon sends out messages of discomfort or disease, when it will be found to be very sensitive.

I learned of this trick twenty years ago from a patient from tropical South America who had been taught the method by a native doctor with a hereditary "degree" only.

Bristol. A. T. TODD.

CIRCULATION IN THE KIDNEY

SIR,—The report by Dr. Trueta and his colleagues recalls four renal cases which I investigated radiologically at a Service hospital in India.

The men were all referred for routine intravenous pyelography, and each showed absence of function on one side. The first two showed normal function on both sides when the examination was repeated after about 48 hours. In neither case was there evidence of calculus formation or other abnormality.

The unilateral cessation of function prior to the first examination was thought to be due to restriction of fluids combined with excessive sweating in the hot climate. It was, however, difficult to understand why this was complete rather than only partial and why it was unilateral. Nevertheless, when further cases with unilateral absence of function were found in which there was no other abnormality, the examination was again repeated within 48 hours, following a more liberal intake of fluids; and two then showed restoration of normal function on both sides. There was no evidence of calculus formation on the original films in either case, and the minor calices, when visualised at the second examination, were normal.

In the light of Dr. Trueta's paper, I am inclined to think that these 4 cases were examples of the device whereby the cortex of a kidney is excluded from the renal circulation, consequent upon diminished blood-volume; in other words, the altered function was simply the result of diminished fluid intake in otherwise normal subjects in a hot climate.

Withington, Manchester. BRIAN DONNELLY.

THE LONDON COLLEGE OF OSTEOPATHY

SIR,—Mr. W. E. Tucker (July 27, p. 145) entirely discredits the theory of osteopathy, while accepting many of the manipulative procedures introduced to England by the osteopaths. His grounds for discrediting the theory are the findings of a select committee of the House of Lords. However august such a body may be, it is hardly one which should be chosen to investigate, clinically and theoretically, a form of therapy.

It is only too patent that while orthopædic surgeons and physiotherapists have adopted some manipulative methods, in large part these have been badly learned. The College sets out to teach qualified medical practitioners all that is best in osteopathy as taught and practised in America.

W. HARGRAVE-WILSON
London College of Osteopathy. Sub-Dean.

SMALLPOX AND VACCINATIO

SIR,—Dr. Boul and Dr. Corfield (August
are to be congratulated on the success with
outbreak of smallpox in Essex in the early
year was controlled and a major epidemic
This is one more illustration of the efficacy
measures for combating smallpox if efficien
out, and it supports the view that smallpox,
the major variety, is, of all the epidemic dise
in this country, one of the most amenable t

This does not mean that all the measures
them were of equal value. Some no doubt
in question the value and advisability of
vaccination campaign. We are told that 15,0
were vaccinated in five days, but we are no
total number for the whole of the campaign.
noted that Dr. Boul and Dr. Corfield make
that the mass vaccination campaign played an
part in bringing the outbreak so satisfactorily
and in this I think they are wise. Results
times been claimed for mass vaccination camp
there was no real evidence to justify the clai
debatable point whether a mass vaccination
involving the vaccination of many thousands
with all the suffering from "bad arms"—not
more serious results—which such a measure
entails, is ever really called for until it is cer
other and less drastic measures have failed. In
to the injury to health there is all the public
upset which such campaigns inevitably engen
would matter less if there was any guarantee t
vaccination campaign would cut short an
but even with the most energetic campaign
always be plenty of people left unprotected t
the outbreak.

In the outbreak of smallpox in the ne
county of Middlesex, reported in the *Britis*
Journal for August 10, 1946, equally satisfact
were obtained without any recourse to mass
of the general population.

Other points in the article by Dr. Boul
Corfield calling for comment are:

1. Of the 4 fatal cases, 2 were vaccinated
had four marks; so even "efficient" vaccin
guarantee against death from smallpox if to
interval has elapsed. In one of the cases t
was only 27 years. Of the 2 fatal cases w
unvaccinated one (R. Pe.), a contact, might ha
death had he not foolishly refused vaccinati
days, when it proved to be too late. It is to
that when compulsory vaccination is repeale
to vaccination, which compulsory vaccination
edly engenders, will gradually disappear, an
close contacts will then refuse vaccination.
good reason to believe that vaccination d
incubation period, if performed early eno
mitigate an attack even if it fails to complete

2. One of the cases (Mr. Rd.) was the sanitar
who arranged the disinfection of the houses an
He had been vaccinated but never re-vaccinate
attack unfortunately proved fatal. Another
a nurse at the smallpox hospital who had a
attack. All members of a public-health staff
have to fight smallpox—doctors, nurses, sanita
tors, &c.—should of course be protected by
vaccinations as a matter of routine.

3. I agree with most of their "Conclusions
I am a little doubtful about no. 3, which deal
question of "marks." I am inclined to think t
of interval since the last vaccination is of more i
than the number of marks. I would rather ma
and often" my slogan. I admit of course t
case of the general public frequent vaccinatio
impracticable, but then I regard immunisat
general population as not the way to protect a c
against smallpox. The case of a public-he
however, is quite different, and they should be
every few years. Indeed, it might not be a b
make it an annual event for the whole staff,
the medical officer of health. After the first v
there would be practically no reaction, so no inco
would be caused.

Leicester. C. KILLICK M

specialised profundities. If he really collaborated and his name appeared at the head of an article, it would not matter because he could be attacked by fellow experts. Dr. Harrison's paper is typical of hundreds others. His experimental work is excellent. The ithmetic of his statistical adviser is beyond reproach. ıt there is no logical cohesion between the two. He d his adviser have unwittingly misled each other. either is to blame. The fault lies in our cultural legacy science split up into water-tight compartments. What true of statistics is equally true of radiology, histology, inical laboratory reports, &c. I want to plead for ore whole-hearted collaboration. Experts must not se touch with general medicine, and general medicine ust learn from experts.

Royal Society of Medicine. DENYS JENNINGS.

SPLANCHNIC BLOCK FOR ANURIA

SIR,—Your leading article of August 17 on the recent ork of Trueta and his colleagues [1] refers to the need r further trial of splanchnic block in anuria. The teresting and attractive explanation of oliguria made ssible by their observations lends belief to the probable enefit from splanchnic block. Nevertheless, caution is eeded in interpreting a diuresis which may follow this ethod of treatment.

In the last two years, we have had 4 cases of severe iguria after abortion, all treated conservatively without ypertonic solutions, splanchnic block, or decapsulation, nd all had a spontaneous diuresis and recovered. etailed biochemical studies were made, and are being eported elsewhere. If splanchnic block had been done owards the climax of their desperate illness, doubtless would have been given the credit for their recovery.

CASE 1.—Single, aged 31. Abortion at 16th week, followed y 10 days oliguria with secretion of only 262 c.cm. urine. lood-urea rose to 550 mg. per 100 c.cm. Excellent diuresis ıen occurred, and complete recovery. Well two years later.

CASE 2.—Single, aged 37. Abortion at 16th week, followed by 4 days severe oliguria with a total secretion of 2360 c.cm. urine. lood-urea rose to 350 mg. per 100 c.cm. Good diuresis then egan and blood-urea returned to normal. Well 22 months later.

CASE 3.—Married, aged 24. Two children. Incomplete eptic abortion at 16th week. Oliguria persisted for 13 days, nd during this time she passed only 1350 c.cm. urine. Like he previous cases, she was extremely ill with vomiting and iccough, and she became œdematous. Blood-urea rose to 00 mg. and the serum potassium to 42·5 mg. per 100 c.cm. he heart became completely irregular and the electrocardioram showed very large T-waves and absent P-waves. Sponaneous diuresis then occurred, and, although colpotomy as necessary for pelvic abscess, she made a satisfactory ecovery, and was well three months later.

CASE 4.—Single, aged 31. Admitted on account of bloodtained vomitus, but found to have an incomplete abortion. he had been losing for a week. The next five days a modertely severe oliguria was noted. Blood-urea rose to 365 mg. er 100 c.cm. A diuresis then began, and her blood chemistry eturned to normal within two weeks. She was quite well 8 months later.

As far as could be determined, these cases were not ue to incompatible blood-transfusion, sulphonamide herapy, or abortifacients. They may have begun as a eflex vascular spasm with cortical ischæmia, and ssibly progressed to thrombosis and cortical necrosis.

In the obstetrical wards there has also been one fatal ase of anuria from cortical necrosis of the kidneys in girl of 16 admitted at term with severe accidental oncealed hæmorrhage. She was delivered of a stillborn hild and developed anuria and died on the third day. splanchnic block with amethocaine hydrochloride was iven on the second day, and repeated on the third day, ut without any effect.

About 1500 deliveries and 400 abortions are admitted nnually at this hospital. In view of our experience it surprising that only 19 cases of acute renal failure ter abortion, and only a total of 52 associated with regnancy, have so far been published.[2]

Obituary

ARTHUR TUDOR EDWARDS

M.A., M.D., M.CHIR. CAMB., F.R.C.S.

Mr. A. Tudor Edwards, who died suddenly at St. Enodoc's, Cornwall, on August 25, won a world reputation by his advancement of thoracic surgery.

Coster

Born in 1890, Arthur Tudor Edwards was educated at Mill Hill School, at Cambridge University, and at the Middlesex Hospital where he was awarded the senior Broderip and university scholarships. From the first it was clear that his bent was surgery. At the Middlesex he worked under the late Sir John Bland-Sutton and Mr. (now Sir) Gordon Gordon-Taylor; the surgery of mangled limbs he learned from the mechanical genius of Meurice Sinclair; and he gained a wide experience of traumatic and general surgery during the first world war, in which he served as a major with a casualty clearing station. After demobilisation he acquired an aptitude for treating the aftermath of operations on the gastro-intestinal tract that must have been the envy of his colleagues. The years of waiting were ended by his appointment to the Westminster Hospital and the Brompton Hospital. His way was not easy; the attitude to thoracic surgery was at that time one of cautious, and indeed justified, reserve which was to be overcome only by proof that major procedures could be undertaken with safety. In his successes with the surgical treatment of bronchiectasis, bronchial and œsophageal carcinoma, and pulmonary tuberculosis, Tudor Edwards provided that proof; and to the Brompton he attracted visitors of all nations, eager to learn his methods.

His reputation was established through his pioneer work in developing techniques which helped to advance thoracic surgery from the occasional reluctant, and always precarious, intervention to the status of an acknowledged specialty ranking with abdominal and other accepted branches of surgery. But he had further claims to recognition: he was a great operator and a teacher of distinction. Those that saw the easy grace of his technique in the difficult procedures that had previously defeated others realised that he was in the front rank of great operators; his associates were perhaps most impressed by the courage and foresight with which he embarked on difficult cases, and by his sound clinical judgment. Really great success in major surgery comes not to the lone worker but to the man who can organise and inspire his colleagues, assistants, and nurses to form one harmonious unit, and in this again he set a great example.

"My first meeting with Tudor Edwards," writes G. M., "was in the early nineteen-twenties, when I sought his help on behalf of a patient with bronchial carcinoma. That first contact made an impression which is still clear; for even at that time he showed the characteristics which were to make him a leader and a pattern for the younger men in his specialty, both in this country and abroad. His manner was grave and courteous, he paid careful attention to my notes of history and clinical findings, to the reports of bronchoscopist and pathologist—and then he crosschecked them all! Essential data must be verified if he did not know and trust those who had recorded them. We were not offended, for it was clear that his one object was the safety of the patient, and this he ensured by every resource he could command. Nothing second-rate would do. He was an outstanding organiser of team-work. Surgeon, physician, radiologist, pathologist, anæsthetist, physiotherapist, nursing staff, surgical assistant—all knew what was expected of them and gave of their best. The patient also was made fully aware of the nature of the

APPEAL FOR MEDICAL AND NURSING JOURNALS

SIR,—Reports and requests from UNRRA missions in Europe make it abundantly clear that the greatest expressed need of doctors in the liberated countries is for medical literature covering the war years, so that they may bring themselves up to date with advances in unoccupied countries.

From time to time appeals for medical literature for individual countries have appeared in the medical press, and the British Council, the Ministry of Information, the Royal Society of Medicine with its microfilm scheme, and other bodies have done something to cope with the problem, but, as a whole, the needs of Europe have hardly begun to be met.

Even if UNRRA could spend its now scanty funds on medical re-education—which it is authorised to do only in the limited sense of informing doctors how to use drugs and other medical supplies supplied by UNRRA with which they may be unfamiliar—a special difficulty arises in the case of British medical and nursing literature on account of the paper shortage.

I am, therefore, appealing for complete sets of general and specialist medical and nursing journals covering approximately the war years. They should be sent to Dr. H. Hadaway, *Room 1934, Health Division, UNRRA*, 19, Portland Place, London, W.1 (Telephone: Langham 3090/341), and carriage will be repaid if requested. If it is felt that the sets cannot be given free of charge, a price should be stated before the sets are forwarded to us and we will try to obtain authority for their purchase. A particular request which we have so far been unable to meet is for a complete set of THE LANCET (1939 to 1945 inclusive) for Hungary.

London, W.1. NEVILLE M. GOODMAN.

PHYSIOLOGY OF CONVALESCENCE

SIR,—I am sure your leading article of August 10 was not meant to imply that convalescence is merely a matter of protein administration. Nevertheless this may be an opportune moment to draw attention to other factors influencing convalescence—namely, the patient's personality and emotional state, and his relationship with his doctor.

Every surgeon is at times confronted by the case where "things will go wrong" despite irreproachable technique before, during, and after operation. In patients who seem to be of equally good physical type the course of convalescence after the same operation may differ enormously. I suspect that it does not entirely depend on postoperative feeding, and I wonder how much attention was paid to emotional factors in the experiments you describe. A surgeon with an indifferent technique (there are some such about) may present some surprisingly good end-results. I am led to believe that personality as well as protein, character as well as calories, play their part. Convalescence being a process of psychic healing as well as tissue healing, it is worthy of study by the psychiatrist as well as the biochemist.

Convalescence on the whole is better conducted by the family doctor, who is more likely to understand the mental make-up and requirements of his patient. Even the specialist surgeon who attaches as much importance to pre- and post-operative care as he does to operative technique (no longer a rara avis) is as likely as any other—perhaps indeed more likely—to disregard his patient's personality. Moreover not all surgeons are equally suitable for all patients; and just as, with free selection, a patient gets the practitioner he deserves, he should also have the surgeon whose personality best fits his own. The family doctor's choice of surgeon is or should be influenced by the surgeon's personality as well as his ability with a scalpel.

To a patient HIS operation is a major event in his life —a milestone if not a tombstone, a turning-point, ominous and fraught with danger. It may come as a climax to a series of mounting fears, or as a devastating bolt from the blue; in any case the trauma is psychic as well as physical. Even after the operation, fears for the future may remain; often a modification or radical change in his life is necessary. These considerations need skilled help, and his convalescence will be influenced accordingly.

Certain operations, moreover, have a special significance to the patient. The loss of the uterus or a breast in the female, prostatectomy or removal of a testicle in the male are examples of mutilating operations, with particular effects on the psyche. In considering cancer, the patient's fear necessitates regard for personality as well as postoperative prognosis. Psychic preparation, suggestion, reassurance, and explanation are as necessary as the choice of pre-anæsthetic or the Fowler position. Here the psychiatrist may well be able to show the influence of personality and reaction-type as well as of neuroses and anxiety patterns in determining success.

Is it too much to hope that the nurse should help more constructively in these problems? At present, and through no fault of her own, her conversation consists of useless if not harmful platitudes, interspersed with blood-curdling reminiscences. Were she brought more into the picture as an intelligent assistant to the tea her constant presence might be used to the mental well as physical benefit of the patient.

Convalescence depends in its final analysis upon t total personality of the individual, and upon his ment and physical make-up, and their reactions to traum These should not be neglected in any study of convalescent problems.

London, W.1. S. CHARLES LEWSEN.

DESOXYCORTONE AND ARTHRITIS

SIR,—Dr. Harrison will always be in trouble with hi statistics until he cultivates the habit of defining hi symbols carefully. His recent calculation (*Lancet* August 10) differs from mine not because either of us i incapable of arithmetic but because the P which he calculates represents among other things the probability of a number of dead rats not developing arthritis. Such a probability is naturally much higher than my estimate based on the behaviour of live rats.

My prolusion was purposely vague to spare Dr. Harrison's feelings. But now he tells us that he has the support of a member of the Institute of Statistical Analysis at Oxford. I trust for the good name of Oxford statistics that I may assume that this adviser never read the paper of Selye (1944) on which the arguments are based. Serious discussion is difficult, because the logic is almost entirely that of Lewis Carroll rather than of Dodgson. This mysterious P, the meaning of which i always changing, is calculated to two places of decimals suggesting accuracy; but it is a matter of arithmetica convenience how it is calculated and the answer depend on the method. This is the sort of thing which Alice found so trying and which made her head go round.

The use made of P is just as startling as the methods of calculating it. Statistics do not prove a hypothesis directly; but if good experimental design reduces possible alternative explanations to two or three, statistical methods may show that all except one are improbable. Dr. Harrison has to choose between Selye's hypothesis that adrenalectomy and thyroidectomy facilitate the production of desoxycortone arthritis and his own hypothesis that their effect is negligible. There is no question of Selye's hypothesis being improbable. It is Dr. Harrison's which is on the borderline of being eliminated. P stands for the maximum probability of Dr. Harrison being right, and his argument can fairly be summarised by saying that he considers that he has afforded statistical proof of his rightness if he can show that the odds against himself are less than 20 : 1; whereas Selye is wrong unless the odds are 20 : 1 in favour. No doubt we shall hear from Dr. Harrison that this is "perfectly valid statistical procedure" and an orthodox application of the nul hypothesis, or another of those numerous phrases with which specialties exert their tyranny. If so, Selye is truly in an unfortunate position. He never attempted to justify his statement statistically but relied on quantitative as well as qualitative differences and on control series represented by a succession of papers in previous years. He also gave a number of subsidiary arguments which led up to his experiments. All these points are unrepresented in the contingency tables which are said to summarise his evidence. In addition, the number of controls in the contingency tables is so small that it is virtually impossible for Dr. Harrison's requirements to be fulfilled.

I must apologise to Dr. Harrison for the Pickwickian vigour of this onslaught. The point at issue is quite important. In medicine, we are always being bullied by the expert behind the scenes who threatens us with ecialised profundities. If he really collaborated and is name appeared at the head of an article, it would ot matter because he could be attacked by fellow xperts. Dr. Harrison's paper is typical of hundreds f others. His experimental work is excellent. The rithmetic of his statistical adviser is beyond reproach. ut there is no logical cohesion between the two. He nd his adviser have unwittingly misled each other. either is to blame. The fault lies in our cultural legacy f science split up into water-tight compartments. What true of statistics is equally true of radiology. histology, linical laboratory reports, &c. I want to plead for ore whole-hearted collaboration. Experts must not se touch with general medicine, and general medicine st learn from experts.

Convalescence being a process of psychic healing as well as tissue healing, it is worthy of study by the psychiatrist as well as the biochemist.

Convalescence on the whole is better conducted by the family doctor, who is more likely to understand the mental make-up and requirements of his patient. Even the specialist surgeon who attaches as much importance to pre- and post-operative care as he does to operative technique (no longer a rara avis) is as likely as any other—perhaps indeed more likely—to disregard his patient's personality. Moreover not all surgeons are equally suitable for all patients; and just as, with free selection, a patient gets the practitioner he deserves, he should also have the surgeon whose personality best fits his own. The family doctor's choice of surgeon is or should be influenced by the surgeon's personality as well as his ability with a scalpel.

To a patient HIS operation is a major event in his life —a milestone if not a tombstone, a turning-point, ominous and fraught with danger. It may come as a climax to a series of mounting fears, or as a devastating bolt from the blue; in any case the trauma is psychic as well as physical. Even after the operation, fears for the future may remain; often a modification or radical change in his life is necessary. These considerations need skilled help, and his convalescence will be influenced accordingly.

Certain operations, moreover, have a special significance to the patient. The loss of the uterus or a breast in the female, prostatectomy or removal of a testicle in the male are examples of mutilating operations, particular effects on the psyche. In considering the patient's fear necessitates regard for personality well as postoperative prognosis. Psychic preparation suggestion, reassurance, and explanation are as neces as the choice of pre-anæsthetic or the Fowler Here the psychiatrist may well be able to show th influence of personality and reaction-type as well as neuroses and anxiety patterns in determining success.

Is it too much to hope that the nurse should help constructively in these *problems?* At present, through no fault of her own, her conversation cons of useless if not harmful platitudes, interspersed *blood-curdling reminiscences.* Were she brought into the picture as an intelligent assistant to the her constant presence might be used to the mental well as physical benefit of the patient.

Convalescence depends in its final analysis upon th total personality of the individual, and upon his me and physical make-up, and their reactions to traum These should not be neglected in any study of conval-cent problems.

London, W.1. S. CHARLES LEWSEN

DESOXYCORTONE AND ARTHRITIS

SIR,—Dr. Harrison will always be in trouble with statistics until he cultivates the habit of defining hi symbols carefully. His recent calculation (La August 10) differs from mine not because either of us is incapable of arithmetic but because the P which he calculates represents among other things the probability of a number of dead rats not developing arthritis. Such a probability is naturally much higher than my estimate based on the behaviour of live rats.

My prolusion was purposely vague to spare Dr. Harrison's *feelings. But now he tells us that he* has the support of a member of the Institute of Statistical Analysis at Oxford. I trust for the good name of Oxford *statistics that I may assume that this adviser* never read the paper of Selye (1944) on which the arguments are based. Serious discussion is difficult, because the logic is almost entirely that of Lewis Carroll rather than of Dodgson. This mysterious P, the meaning of which i always changing, is calculated to two places of decimals suggesting accuracy; but it is a matter of convenience how it is calculated and the answer depend on the method. This is the sort of thing which Al found so trying and which made her head go round.

The use made of P is just as startling as the method of calculating it. Statistics do *not* prove a hypothe directly; but if good experimental design reduc possible alternative explanations to two or three, statistical *methods may show that all except one* are improbable. Dr. Harrison has to choose between Selye's hypothesis that adrenalectomy and thyroidectomy facilitate the production of desoxycortone arthritis and his own hypothesis that their effect is negligible. There is no question of Selye's hypothesis being improbable. It is Dr. Harrison's which is on the borderline of be eliminated. P stands for the maximum probability of Dr. Harrison being right, and his argument can fairly be summarised by saying that he considers that he has afforded statistical proof of his rightness if he can s that the odds against himself are less than 20 : 1; whereas Selye is wrong unless the odds are 20 : 1 in favour. N doubt we shall hear from Dr. Harrison that this is "perfectly valid statistical procedure" and an orthod application of the nul hypothesis, or another of the numerous phrases with which specialties exert their tyranny. If so, Selye is truly in an unfortunate position. He never attempted to justify his statement statistically but relied on quantitative as well as qualitative differences and on control series represented by a succession of papers in previous years. He also gave a number of subsidiary arguments which led up to his experiments. All these points are *unrepresented in the* contingency tables which are said to summarise his evidence. In addition, the number of controls in the contingency tables is so small that it is *virtually impossible* for Dr. Harrison's requirements to be fulfilled.

I must apologise to Dr. Harrison for the Pickwickian vigour of this onslaught. *The point at issue* is quite important. In medicine, we are always being bulli by the expert behind the scenes who threatens us with rhaps May's many gifts," writes D. C. N., "were 'ed to the best advantage during the international ss on Life Assurance Medicine in 1938, when he as chairman of the organising committee. His live contacts with colleagues abroad and his rity with their languages and special work and ts, were invaluable in selecting speakers and ing the programme. His quiet humour and failing courtesy went far to ensure the smooth ıg of committees under his chairmanship. He ; had a smile and a kindly word for the younger rying to find their feet in this rather perplexing n's-land between the worlds of scientific medicine shrewd business, and he combined most happily isdom and caution of long experience of the effects rbid conditions on life expectation with an alert st in modern methods of research and treatment."

his work for the British Social Hygiene Council rummond Shiels writes: "In the first world war, ent his full energies to Mrs. Neville Rolfe and to rganisation she founded (afterwards the British Hygiene Council) in the fight against the taboos prejudices—inside and outside the profession— hindered effective measures for the prevention reatment of the venereal diseases. Thereafter, in gs and in speech, and often with little official rt, he continued his work for the council in the years between the two wars, and at his death he chairman of its executive committee. He also red substantial service to the Central Council for h Education, when that body assumed responsibility .D. propaganda. He lived not only to see the eal diseases take their appropriate place among al problems, but also to be cheered by new and ising treatments. He had a very happy family nd was always prepared to fight against forces or tions which prevented happy family life for others. ıg the late war he returned to duty from his retire- and led a team in long and strenuous days of al examination of recruits for the Services. In his but effective way he did something for public health or human happiness which his friends will remember pride and gratitude."

. May married Miss G. Mabel Rose and they had ions.

Births, Marriages, and Deaths

BIRTHS

IAW.—On Aug. 29, in Liverpool, the wife of Mr. H. Bernard agahaw, F.R.C.S.E.—twin daughter and son.

—On Aug. 26, at Oldham, Dr. Margaret Binks (née Jackson), ie wife of Dr. Paul Binks—a son.

N.—On Aug. 21, the wife of Dr. John Brown, of Bedlington— son.

KLIN.—On Sept. 1, at Edgware, the wife of Dr. C. B. Franklin —a son.

IAN.—On Aug. 26, in London, the wife of Dr. J. Esmond Iurman, R.A.F.V.R.—a son.

ONALD.—On Aug. 29, at Stanwix, Carlisle, the wife of Dr. Ian Iacdonald—a son.

AINE.—On Aug. 26, at Retford, the wife of Wing-Commander . V. Maclaine, M.B., R.A.F.—a son.

UGHLIN.—On July 19, in Dublin, the wife of Lieut.-Colonel . E. McLaughlin, I.M.S.—a daughter.

RSON.—On Aug. 30, at Whitchurch, Shropshire, Dr. Evelyn togerson, wife of Dr. Gerard Rogerson—a daughter

NBERG.—On Aug. 24, at Worthing, the wife of Dr. Henry tosenberg—a daughter.

AMORE.—On Aug. 26, at Macclesfield, the wife of Flight-Lieutenant T. O. Scudamore, M.B.—a son.

Y.—On Aug. 25, in London, the wife of Dr. Rupert Solley— son.

E.—On Aug. 28, the wife of Dr. Douglas Teare, of Midhurst— son.

ER.—On Aug. 30, at Kingston, the wife of Dr. G. D. Walker —a son.

H.—On Aug. 29, at Milton, Suffolk, the wife of Dr. Rodney Valsh—a daughter.

G.—On Aug. 24, at Nottingham, the wife of Dr. J. Horton oung—a daughter.

MARRIAGES

LE—BRYANT.—On Aug. 28, at Henbury, Bristol, Edward Vilson Carlile, B.D., to Elizabeth Bryant, M.B.

ER—COX.—On Aug. 22, at Watford, Keith E. Cooper, M.B., o Eileen Mary Cox.

Y—BELDAM.—On Aug. 24, in London, Roger Anderson rownsword Drury, B.M., to Gillian Beldam.

N—WEDDELL.—On Aug. 29, at Colchester, François Edward Iortimer Puxon to Margaret Weddell, M.R.C.O.G.

DEATHS

ELL.—On Aug. 26, at Ambleside, Thomas Houghton Mitchell, .D. Durh., aged 83.

Notes and News

THE DENTIST'S INCOME

THE Minister of Health and the Secretary of State for Scotland have appointed a committee of nine members, including four dentists, under the chairmanship of Sir Will Spens, to recommend "what ought to be the range of total professional income of a registered dental practitioner in any publicly organised service of general dental practice." The Minister has further written to Sir Will Spens stressing that the terms of reference do not bind the committee to base their recommendations on what dentists have earned in the past, but make it clear that the committee should state what in their view the remuneration of dentists should be if the proper social and economic status of general dental practice is to be maintained in the future, and if the profession is to attract suitable recruits.

TREATMENT OF RECURRENT HERPES

RECURRENT herpes is seldom a serious disease, but it causes discomfort and disfigurement for days at a time and as such may be a lifelong burden. The treatment consists in finding a satisfactory local application. Dr. Arthur Whitfield writes: "The application of a drying powder, which is the usual treatment, has, I think, very little effect; and ointment simply increases the sensation of heat and often leads to suppuration. Attacks are generally preceded by premonitory sensations of burning and itching. I found that tar solutions applied at this stage help to abort the attack; and, after several experiments, I settled finally on a water-soluble varnish, 'Pellanthum,' to which is added 10% of liquor picis carbonis, made up by Messrs. Handford and Dawson, Harrogate. This can be carried about and easily smeared over the affected area, the resulting film being almost invisible. There is no evidence that the treatment removes the tendency to relapse, but it does at least ease the lot of those that suffer from this tiresome disease."

University of Cambridge

Dr. M. Hynes has been appointed reader in medicine, from Oct. 1 next. Dr. C. L. G. Pratt has been appointed university lecturer in mammalian physiology, and Dr. G. P. McCullagh, university lecturer in pathology. Mr. A. L. Hodgkin, M.A., has been appointed temporary university lecturer in physiology, and Dr. H. Butler temporary university demonstrator in anatomy.

University of London

As already announced, the title of professor of clinical pathology in the university has been conferred on Dr. R. J. V. Pulvertaft, in respect of the post held by him at Westminster Hospital medical school.

Dr. Pulvertaft is 49. After leaving Westminster School he served from 1915 to 1919 in the Royal Sussex Regiment, being seconded to the Royal Flying Corps and R.A.F. as observer (Palestine) and pilot (B.E.F.). At the end of the war he went up to Trinity College, Cambridge, where he had won a scholarship in classics, and after taking the second part of the natural sciences tripos, in physiology, he went to St. Thomas's Hospital as a university scholar. Having qualified in 1923 he became assistant bacteriologist in the venereal diseases department and was pathologist to the medical and surgical units from 1923 to 1932, holding a Plimmer research fellowship for part of this time. In 1932 he was appointed director of the J. B. Carlill laboratories at Westminster Hospital, and reader in pathology in the University of London. He became M.R.C.P. in 1927, M.D. in 1933, and F.R.C.P. in 1938. During the late war he served in the Army, chiefly in Egypt and Palestine, and was for a time assistant director of pathology, Middle East Forces. In 1944 he was appointed O.B.E. His original observations have been largely concerned with the behaviour of streptococcal and other infections; before the war he made a special study of aerosol disinfection, and of late he has worked on penicillin. He was for several years editor of *Discovery*.

As already announced, the title of professor of physiology has been conferred on Mr. W. R. Spurrell, F.R.C.S., in respect of the post now held by him at Guy's Hospital medical school.

Mr. Spurrell graduated B.SC. Lond., with first-class honours in physiology, in 1931. He studied medicine at Guy's Hospital, qualifying M.R.C.S. in 1924, and M.B. Lond., with gold medal and distinction in surgery and pathology, in 1925. The following year he graduated M.S., and passed his final examination for the F.R.C.S. At Guy's Hospital he held appointments as outpatients officer, house-surgeon, demonstrator in anatomy and physiology, and surgical registrar; he was also awarded the Parsons research fellowship. Subsequently, in the University of Leeds, he was research assistant in the department of experimental pathology from 1928 to 1930, and was demonstrator in physiology before taking up his present appointment at Guy's Hospital. He is the author of numerous articles, and has taken a special interest in the physiology of the alimentary tract.

operation planned, of its risks, and of any disabilities it would entail. His full coöperation was obtained in a carefully planned course of preoperative and post-operative treatment. Tudor Edwards, or "Tudor" to his friends, could act with the utmost decision and despatch; but action was quiet and seemingly unhurried. His manner in the operating theatre was typical of the man—decisive, but gentle and considerate. I never heard him speak impatiently or unkindly to those who were assisting him."

His published work gives some idea of his vast experience in the last twenty-five years. Thus his last important paper, in the first number of *Thorax*, contains an analysis of over a thousand cases of bronchial carcinoma, in 70% of which he had performed either pneumonectomy or lobectomy. He was the first surgeon in this country to perform with success lobectomy by dissection; and he had already had many successes with tourniquet lobectomy before its general introduction in 1931. He was the first surgeon in this country to perform a pneumonectomy; and he was among the first—if not actually the first—to report successful resection of the carcinomatous œsophagus. He is also known for his fundamental contributions to the treatment of empyema.

In 1936 the London Hospital invited him to organise a department of thoracic surgery, and he resigned from the Westminster Hospital to concentrate on his specialty. As consultant thoracic surgeon to the L.C.C. he was responsible for founding the successful unit at St. Mary Abbot's Hospital. He was also surgeon to King Edward VII Sanatorium, Midhurst, and was attached to Queen Alexandra's Hospital, Millbank. The strain of these many activities, along with that of a busy consultant practice, inevitably took its toll. In 1938 he had a severe illness, but made a good recovery. In the autumn of 1939, however, he again fell ill. Even this did not deter him from once more throwing all his energies into work during the second war. He was obliged to limit his operating, but, as consultant adviser to the Ministry of Health, took an active part in the founding of centres for the reception of thoracic casualties throughout Great Britain; these have proved so valuable that it is difficult to see how they can be dissolved. As civilian consultant to the R.A.F. he founded a special centre; he was also consultant thoracic surgeon to the War Office, and served on many committees. In 1939 he was awarded the honorary degree of M.D. by Grenoble University, and in 1943 was appointed to the council of the Royal College of Surgeons. He was a past president of the Association of Thoracic Surgeons, and was recently elected first president of the Association for the Study of Diseases of the Chest, which owes its origin largely to his inspiration and enthusiasm. Only this year the degree of M.D. was conferred on him, honoris causa, by the University of Oslo, which, during his last illness, sent him a gold ring. He is survived by his widow.

G. G.-T. writes: "Those who have been reckoned great in surgery must of necessity be supremely skilled in the craftsmanship of our profession; they must by the initiation of some novel and successful system of treatment or by the operative invasion of territories hitherto unconquered have conferred untold blessing on mankind; their work must have illumined the dark, mysterious chasms in our knowledge of disease; but they must also have trained and inspired a band of surgical acolytes. Tudor fulfilled these criteria right well; his operating theatre became a Mecca not only for thoracic surgeons but for general surgeons from all over the world." "Sincerity and directness of purpose," adds a colleague, "were unmistakable in his character, and one feels that he would ask no greater memorial than the realisation of how much the chest surgery of today owes to his efforts."

Surgeon Commander W. T. GWYNNE-JONES, R.N., was one of the five occupants, all of whom lost their lives, when a Royal Naval Air Ambulance crashed on Mickeldore Crags, near Scafell, while carrying a patient from Abbotsinch naval air station to Warrington. Commander Gwynne-Jones, who was 54 years of age, qualified at the London Hospital in 1915.

HARRIE LESLIE HUGO SCHÜTZE

M.B. MELB., M.D. WÜRZBURG

Dr. Harrie Schütze, who died at Berne, in Switz
on August 9, was born in Melbourne in 1882, th
of a German father and an English mother. Edu
at Brackley and Cumloden, he graduated M.B. a
University of Melbourne in 1905. Continuing his m
education he took his M.D. at Würzburg two years
and became assistant in the Institute of Hygiene in
city. In 1912 he was elected to a Beit fellowship a
the following year he was appointed to the staff o
Lister Institute of Preventive Medicine in the ba
logical department, where he remained througho
professional life. For many years towards the e
his service Schütze was in charge of the vaccine de
ment of the Institute, a position for which his n
bent, training, and experience well fitted him.

One of his colleagues writes: "A competent ba
logist and a careful, thorough, and conscientious in
gator, he was so critical of his own work th
results, though obtained in somewhat specialised f
stand today as he left them. His early work, larg
an orientating character, stressed the importance
reality of the different members of the salmonella
of organisms and brought order into a field which
becoming confused. Later he showed the importa
of the envelope of the plague bacillus in the antigenic
of the vaccines made from it, and he also demonstrat
the essential differences between those otherwise clos
related micro-organisms, *Pasteurella pestis* and *P*
pseudotuberculosis.

"In 1913 Schütze married Henrietta Leslie, the nove
and playwright. They shared common interests
art, music, literature, and travel, and, apart from
war when they lived at Radlett, they entertained
friends, in a style and manner not soon to be forgot
in their charming house in Chelsea. Of a quiet, stu
and retiring disposition, with a pleasant subdued
and a cultured, courteous manner, Schütze's fa
often moved him more deeply than appeared o
surface; his concern for the persecuted and dispos
scholars of Europe was real, as were his efforts to re
their distress."

OTTO MAY

M.A., M.D. CAMB., F.R.C.P.

Dr. Otto May, chairman of the British Social Hy
Council, died on August 15. As a former principal me
officer of the Prudential Assurance Company he
an established position in the insurance world, but
brilliant academic career was unknown even to man
his friends, while his modesty and concern with a
time unpopular medico-sociological problems obs
his professional ability and attractive personality.
in 1879, the second son of the late William May,
was educated privately. Entering St. John's Co
Cambridge, with a foundation scholarship he too
first in both parts of the natural sciences tripos
after holding a demonstratorship in physiolog
Cambridge completed his medical education at Univ
College Hospital. He qualified in 1907 and was aw
the Atchison scholarship and the Liston medal.
spending a year in house-appointments at U.C.H.,
became in 1908 medical registrar at the Midd
Hospital, and the following year physician to outpat
at the Evelina Hospital for Children. To this p
while he held a B.M.A. research scholarship and a
fellowship, belong his papers on sensory disturba
of heart disease, the mechanism of cardiac pain,
posterior root section for the treatment of spasticit

When he joined the Prudential Assurance Compan
1912 he thus brought to his new work a backgrou
clinical experience and scientific training which qu
won recognition. He served the Assurance Med
Society as secretary for many years, and in 1920 in
presidential address, assessing the progress of
assurance medicine, he urged doctors to provide
actuaries with data on which to base more accu
assessments of mortality. Dr. May also discussed in
columns tuberculosis in relation to life assurance
the value of periodical medical examinations. He
an honorary member of the Association of Life Assur
Medical Directors of America.

PAINFUL FEET

PRISONERS-OF-WAR IN THE FAR EAST

REVIEW OF 500 CASES

E. K. CRUICKSHANK
M.B. Aberd.
ı the Department of Medicine, University of Aberdeen

symptom known as "painful feet," "burning "aching feet," "sore feet," and "happy feet" ppeared among prisoners-of-war in Changi Camp, ore, at the end of July, 1942—i.e., five and a half s after their capture. Some of the Malayan doctors t in the camp were already familiar with it, and r and Pallister (1935) had described it in inmates local jails who were on a diet deficient in vitamin B ad noted that the pain disappeared when green bles were added to the diet.

following account is based on the records of 500 personally observed.

SYMPTOMS

ı of two types was felt in the feet :

A dull ache was usually the earliest abnormality as felt below the heads of the metatarsals and in the of the toes. At first it was present only at night a long day's standing or walking, developing as atient was trying to sleep. As the days passed, he became more pronounced, coming on in the early ng and increasing when the patient retired to bed. as variously described as aching, burning, or bing.

Sharp stabbing pains became superimposed on the in 58·6% of the 500 cases. A single pain lasted sec., shooting, parallel to the toes and soles of the nto the heels, through the ankle-joints, and some- up the shins to the knees. In 6·4% there were r symptoms in the hands, but these usually developed in long-standing cases 4–8 weeks after the onset nptoms in the feet.

the condition progressed, the ache or burning sensa- ecame constant, being present all day, getting worse evening, when the shooting pains began to appear. pains reached their maximum when the patients to bed, and often prevented sleep, at first for 1–2 , but later, in the severe cases, throughout the Exercise relieved the pain considerably for a so many patients got up and walked around most e night. Some put their feet in cold water or ged them, whereas others preferred warmth. ese measures, however, gave very temporary relief ; as time passed, the patients became worn out, red and irritable from loss of sleep and constant pain. this stage, usually several weeks after the onset, ppetite rapidly became poor in many of the men, hese often showed pronounced lassitude and loss ight.

rly 80% of the patients gave a previous history of iciency state of the vitamin-B_2 type—stomatitis, tis, scrotitis, or defective vision.

SIGNS

eral.—In the early case the general condition was unless there had been some recent debilitating e, such as severe dysentery or chronic malaria, on precursors of the syndrome. In the established ic case there was evidence of rapid loss of weight. ace had a strained worried look, with dark shadows the eyes, the result of constant pain and lack of Some patients were nervous and jumpy, particu- t any prospect of having their feet examined.

incidence of associated deficiency conditions in 0 cases reviewed when they came under observa- as as follows.

)

Vitamin-B_2 deficiency	
Scrotitis	30·0%
Stomatitis (angular stomatitis, glossitis, lesions of buccal mucosa, palatal erythema)	31·6%
Defective vision (the result of retrobulbar neuropathy)	13·0%
Vitamin-B_1 deficiency (8·0%)	
Œdema	6·2%
Neuritic signs :	
Absent or sluggish reflexes	2·2%
Hypalgesia of legs	1·8%
No associated deficiency disease	42·0%

Diarrhœa was not an associated condition in the cases reviewed, though 36% had a history of one or two attacks of dysentery. Most of the patients were outpatients, only severe cases being admitted to hospital. Cases occurring in hospital patients with some other disease, such as chronic dysentery or malaria, are excluded.

Feet and Legs.—No abnormality of the feet and legs was seen in the great majority of cases. Some feet were red, some pale, some somewhat bluish ; but, when the feet of 50 patients with painful feet were compared with those of 50 persons without painful feet, an equal variety of hue was found in the skins of the controls. There was no evidence in the skin of vascular spasm or of trophic changes. Most of the feet were warm, and the dorsalis pedis and posterior tibial arteries were easily palpable. The capillary circulation appeared normal, in that an area blanched by pressure rapidly recovered its colour on release of the pressure. Some patients had deformities of the feet—various degrees of flat-foot and hallux valgus—but the proportion was no higher than in a group of controls. In a few of the severe cases the feet sweated excessively, and, if they were dried, visible beads of sweat again appeared in a few minutes. Some patients in hospital adopted a characteristic attitude in bed. They sat forwards in a half-squatting position, gripping their toes in their hands. They were extremely nervous of having their feet examined and withdrew the foot rapidly if they were lightly touched. Hypersensitivity to pinprick and light touch was present in about 22·2%, but in most of these, if the feet were firmly gripped and handled, there was no complaint of pain. Cramps and muscle spasm were rare, and there was no muscular tenderness.

Nervous System.—Tendon reflexes were exaggerated in 23%, and in most of these cases the reflexes were affected in the arms as well as legs, even when there were no pains in the hands. In these patients the slightest tap with a reflex hammer produced a very brisk response ; in some cases 3–10 clonic movements of the ankles (and, in a few, of the patella) were elicited when clonus was tested for. The abdominal reflexes were present in all cases and usually brisk. The plantar responses were usually flexor, but in some cases an equivocal response was repeatedly found; the feet in those cases were extremely sensitive, and pronounced withdrawal was associated with such responses. The exaggerated reflexes developed gradually in the course of the disease, becoming apparent on an average 3–6 weeks from the onset of symptoms, though some cases showed this feature at the first examination. Of the 51 cases which showed hypertension (discussed below) 39 had exaggerated reflexes, and 12 had reflexes within normal limits—i.e., 76% of all cases with hypertension, as compared with 23% of the whole series, showed increased reflexes.

The gait in severe cases was slow and hobbling because of the pain but showed considerable individual variation. In 2·2% the tendon reflexes were absent or very sluggish, and in 1·8% hypalgesia of the feet and legs was found ; these were regarded as cases of associated vitamin-B_1 deficiency. No other sensory changes were present.

Cardiovascular System.—In 9 cases there was tachycardia (pulse-rate 90 or more per min. after the patient

Society of Apothecaries of London

At a court of assistants held on August 20 with Dr. H. F. Powell, the master, in the chair, Dr. C. T. Parsons was elected master for the ensuing year, and Dr. J. P. Hedley and Prof. E. C. Dodds, F.R.S., wardens. Professor Dodds was appointed representative at the British-Swiss Medical Congress at Bâle, and Sir Cecil Wakeley on the governing body of the British Postgraduate Medical School and the proposed British Postgraduate Medical Federation.

It was unanimously resolved to award the society's gold medal in therapeutics for 1946 to Sir Alexander Fleming, F.R.S., and Sir Howard Florey, F.R.S., in recognition of their discovery of penicillin.

The following were admitted to the freedom of the society:

By Redemption: Richard Clitherow, M.P.; B. J. Frankenberg; Lord Amulree; A. J. Rook; C. W. F. McKean.
By Servitude: G. M. Woodwark.

The following were appointed examiners: pathology, R. W. Scarff; midwifery (deputy examiner), Anthony Charles; chemistry, Phyllis Sanderson. The following diplomas were granted:

D.I.H.—A. Anderson; K. Biden-Steele; M. P. Fitzsimons; O. G. Bennett; G. F. Keatinge.

L.M.S.S.A.—F. W. Flight; D. Rivers; C. M. M. Severn; P. R. Needham; I. T. Holloway; A. Macarthur; F. Deutscher; D. A. Bailey; H. Walker; G. Steinberg; R. Cartledge; W. F. Belsham; *J. M. Jones; C. C. Gibbons*; R. N. H. *Vann*; R. M. *Michelmore*; R. M. Jenkins; E. J. Rich; A. Culiner; J. L. Struan-Marshall; K. R. W. Miller.

London Hospital

From Oct. 16 to 19 a postgraduate course for former students will be held at the hospital. Those who wish to attend should notify the dean as soon as possible. The annual dinner will take place on Thursday the 17th, at 7.30 P.M., at Claridge's Hotel, Brook Street, London, W.1, when Sir Henry Bashford will be in the chair.

International Conference in London

An international medical conference is to be held at B.M.A. House, Tavistock Square, from Sept. 25 to 27, to consider the promotion of closer ties among the national medical organisations in the different countries. The conference is being convened by the British Medical Association in conjunction with the Association Professionnelle Internationale des Médecins. The languages will be English and French, and an interpreter will be present.

Aslib Conference

Sir Reginald Stradling, F.R.S., president elect of the association, will open the 1946 conference at the Polytechnic, 309, Regent Street, London, W.1, on Saturday, Sept. 14, at 10.30 A.M. Further information may be had from ASLIB office, 52, Bloomsbury Street, W.C.1.

Royal Sanitary Institute

The institute will hold their 1947 Health Congress at Torquay, from June 2 to 6, under the presidency of Earl Fortescue.

London Scientific Film Society

During the coming session, beginning this month, the society will show scientific and documentary films on Sunday afternoons and evenings; it also hopes to arrange for lectures and the showing of research films on weekdays. Among other proposed activities are the organisation of scientific films for children, the publication of a quarterly journal, and the production of experimental films. Inquiries should be directed to the society at 34, Soho Square, London, W.1.

Merseyside Telephone Bureau

Doctors who have no-one at home to answer their telephones have set up a central bureau in Rodney Street, Liverpool, where urgent messages can be left. They will keep in touch with the bureau while on their rounds and receive any messages which have been sent during their absence. The *Daily Express* (August 27) states that the new service, which is staffed mainly by former medical orderlies and telephonists from the Forces, will cost each doctor £20 a year.

17th London British General Hospital

A reunion dinner of this hospital will be held at Oddenino's Restaurant, Piccadilly, London, W.1, on Oct. 25, 1946. Tickets can be obtained from Dr. C. H. Atkinson, 53 Park Street, W.1; Dr. D. Blatchley, 2 Chatsworth Road, W.4; Dr. S. P. Rea, 84 Banstead Road, Carshalton, Surrey.

Return to Practice

The Central Medical War Committee announces t
following have resumed civilian practice:

Mr. A. SEYMOUR PHILPS, F.R.C.S., 104, Harley Street,
Mr. A. H. M. SIDDONS, M.CH., F.R.C.S., 140, Harley S

gering and exaggeration of symptoms were difficult clude. Only by careful observation and certain could these be detected, and there is no doubt ome patients made the most of their symptoms to camp fatigues and heavy work.

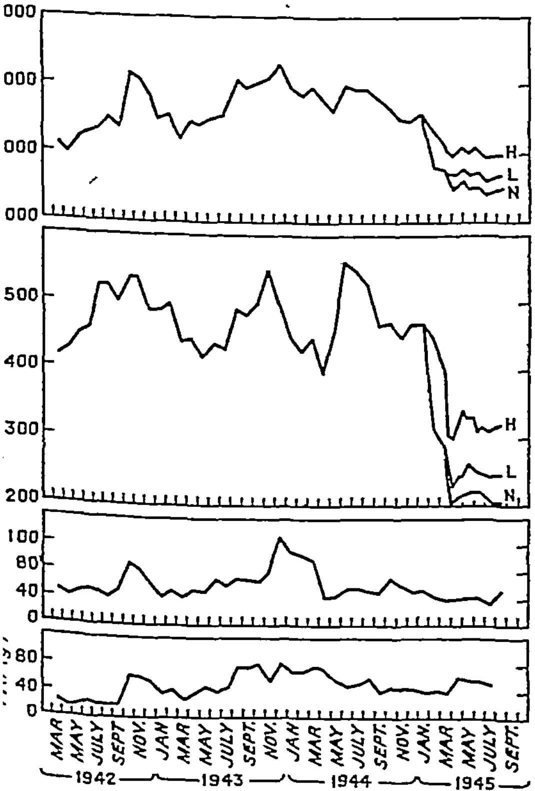
en Gram.—In 20 chronic cases 8 oz. of boiled green was given daily for various periods. These cases all relatively severe and of long standing, and were n because a considerable amount of weight had been The results were as follows:

In 11 cases there was considerable improvement in an ge of nineteen days. Of these, 2 had had five nicamide ions of 1·7 c.cm. intravenously before the green gram, slight improvement in 1 and none in the other. One r patient, owing to his severe symptoms, was given a of five nicamide injections while receiving green gram, ith no improvement.

In 7 cases there was some improvement in an average nty-nine days. Of these, 1 improved considerably when ide was given, and 2 showed no improvement with ide.

In 2 cases there was no improvement in an average of -five days. Of these, 1 had had nicamide before the gram, with no improvement. The other was given ide after thirty-one days on green gram and was con-bly improved.

ce Polishings.—In 323 cases 3 oz. of rice polishings given daily. This dose was chosen because it was average maximum amount that could be taken patient in a day. In many cases a larger dose uced diarrhœa and abdominal discomfort. It was easant material to take; and, since most of the nts received their dosage as outpatients, it was ult to make sure that the full daily dose was taken; patients were actually caught trying to dispose of it. must be taken into consideration in assessing results. the 323 cases treated with rice polishings none was letely relieved; 128 (39·6%) showed considerable ovement after an average of six weeks' treatment, the time varying from two to twelve weeks; 51 (15·8%) showed some improvement in the same average period; 144 (44·6%) were not improved or worse. In the first two groups a few patients relapsed while still on rice polishings.



1—Calories, carbohydrates, proteins, and fat in daily ration: , heavy-duty ration; L, light-duty ration; N, no-duty ration.

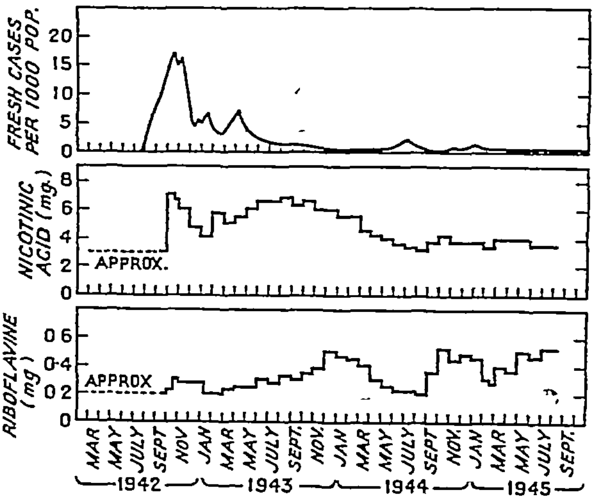


Fig. 2—Incidence of fresh cases of painful feet per 1000 of population compared with amounts of nicotinic acid and riboflavine per 1000 calories of diet.

Marmite.—To 38 patients 1 oz. of marmite was given daily by mouth. None was completely relieved; 21 (55·3%) showed considerable improvement in three weeks; 5 (13·2%) were considerably improved after an average of twenty-six days; and 12 (31·5%) were not improved after two weeks' treatment.

The results of treatment are summarised in the accompanying table.

CONTROLS AND FOLLOW-UP

Unfortunately no true control group was kept in which no treatment whatever was given, because the condition was considered to be a vitamin-deficiency syndrome from the first, and it was not regarded as justifiable to withhold treatment. However, cases occurred outside our camp in isolated areas where no specific source of extra vitamin B was available; in these no considerable improvement took place until better rations were supplied, when the symptoms gradually became less severe and eventually disappeared.

It was impossible to follow up the cases indefinitely, and a considerable number of the patients who had not much improved left for other camps while under observation. The incidence graph (fig. 2) shows that there was a sharp fall in the number of fresh cases at the end of November, 1942, when Red-Cross supplies became available, and thereafter there was a considerable general improvement in the diet as the camp personnel began to receive pay from the Japanese. It became possible to supplement considerably the basic Japanese ration with locally purchased foods, such as green gram and groundnuts. With this improvement in the diet the cases which had not responded to specific treatment gradually improved, and by July, 1943, the syndrome had almost disappeared from the camp. Nor did a wave of fresh cases occur thereafter.

However, 6 patients seen three years after the onset said that their feet had not quite returned to normal. They complained of occasional aches in the feet at night, with stabbing pains at times. The symptoms were often worse in cold or wet weather.

The abnormal briskness of tendon reflexes, where present, gradually became less as the pain disappeared, but there was usually a lag of one or two months in those cases where the disappearance of pain was rapid.

RESULTS OF TREATMENT OF 500 CASES OF PAINFUL FEET WITH VITAMIN-B SUPPLEMENTS

No. of cases	Treatment	Approx. content of—			Results of treatment								Remarks
		Vitamin B_1 (µg.)	Riboflavine (mg.)	Nicotinic acid (mg.)	Complete relief		Much improved		Improved		No change or worse		
					No. of cases	Average time	No. of cases	Average time	No. of cases	Average time	No. of cases	Average time	
119	Nicamide 2 c.cm. 5–8 daily i.v. injections	..	..	340	20	During or within a few days of injection	62	During or within a few days of injection	19	During or within a few days of injection	18	..	Mostly given rice 2 oz. daily injections within 1-2
20	Boiled green gram 8 oz. daily	750–1000	3·3	2	..	..	11	19 days	7	29 days	2	35 days	All severe long hospital
323	Rice polishings 3 oz. daily by mouth	2500	0·25–0·5	20–40	..	..	128	6 weeks	51	6 weeks	144	6 weeks	Mostly

had been lying down for half an hour). Of these, 1 had associated hypertension alone, 3 had hypertension with exaggerated reflexes, 2 had hypertension with absent reflexes, and 3 normal blood-pressures and normal reflexes. None of the cases showed evidence of organic heart disease.

Of 189 cases in which the blood-pressure was recorded, 51 gave readings that were considered hypertensive.* (The upper limit of normality was arbitrarily placed at 130/90 mm. Hg; the average reading for 500 subjects without sore feet over the same period was 121/78.) The average age of the patients with hypertension was 28 years (oldest 42, youngest 21). The average blood-pressure in the hypertensive cases was 142/104 mm. Hg (highest 200/142). The average reading for the other 138 cases in which blood-pressure was recorded was 118/76 mm. Hg.

In all the cases with hypertension the symptoms were severe and of long standing. In this group the feet had been painful for 1–5 months (average 2½ months); the average loss of weight, during 6–18 months' imprisonment, was 3½ st. (maximum 7 st. 4 lb., minimum 9 lb.); in all cases sleeplessness had lasted more than a month, in some for as long as three months; and in 49 out of the 51 the appetite had been poor for a month.

In 11 of the 51 patients hypertension developed under observation. In the rest it was present when the first blood-pressure reading was taken; these were usually men who had been held on the lines as long as possible and referred to hospital only when they became unfit for duty.

No albumin was found in the urine of any of these cases.

TREATMENT

When the pains in the feet first appeared they were assumed to be a result of a deficiency of vitamin-B complex, in view of the findings of Landor and Pallister (1935).

General.—All the patients were rested as far as possible. Those with milder symptoms were taken off duties which involved standing or walking. Those with more severe symptoms were admitted to hospital and kept in bed, except for bathing and going to the latrines. This was very difficult to enforce, because of the temporary relief obtained from exercise, and the men often slipped out of bed and were found walking round and round the buildings.

Diet.—The patients received the ordinary camp diet, the calculated calorie value and food content of which are shown in fig. 1. Available extra sources of vitamin-B complex were as follows.

Rice polishings.
Green gram (*Phaseolus radiatus*)—one of the pulse
Extract of green leaves.
Ground-nuts (available in small quantities only).
Soya bean (available only after the major wave passed).
'Marmite.'
'Nicamide' (B.W. CO.) (nikethamide, the diethylamide nicotinic acid); 2 c.cm. is equivalent to 340 mg. nicotinic acid.
Synthetic crystalline vitamin B_1 (in small quantities

RESULTS

Crystalline Vitamin B_1.—In 6 cases 2 mg. was daily intravenously for seven days, but no improvement resulted. Owing to very limited supplies and the occurrence of frank beriberi in the camp no cases of painful feet were treated by this method.

Nicamide.—In preliminary experiments with it was found that no improvement resulted from stration by mouth. Intramuscular injection improvement, but intravenous injection produced most rapid and satisfactory results. A daily 1·7 c.cm. was given intravenously for 5–10 consecutive days in 110 cases. These were divided into two groups

(1) In 98 chronic cases (symptoms present month or more) results were as follows:

(*a*) 10 patients obtained complete relief, except sional aches, for two months. The symptoms disappeared, usually after the fourth or fifth injection response did not occur immediately on injection. has no immediate peripheral vasodilator effect nicotinic acid.

(*b*) 54 patients showed considerable improvement were able to sleep, and the sharp shooting pains occasional or disappeared. Of these cases 12 relapsed a week of completing the injections in spite of 2 oz. polishings daily. (In groups (*a*) and (*b*), when pos patients were given 2 oz. of rice polishings daily for months after the injections.) Of these 12 patients, bad as ever, and 7 were partially relieved.

(*c*) 16 patients showed some improvement. The pains became less frequent, and they could get some night.

(*d*) 18 patients showed no improvement.

(2) In 21 acute cases (treatment instituted three weeks of onset) results were as follows:

(*a*) 10 patients obtained complete relief except for aches, but 3 of them relapsed ten, seventeen, and days after the last injection.

(*b*) 8 patients showed considerable improvement.

(*c*) 3 patients were slightly improved.

To 10 patients, used as controls, 2 c.cm. of water was given intravenously daily for five said there was slight improvement.

Since the severity of the condition had to be to a considerable extent by the patient's statem

rom the Department of Medicine, University of Edinburgh

MUCH attention has been aroused by recent reports Spies (1946) and others on the use of *folic acid* in galoblastic anæmias of various types: the work has n summarised in recent articles in this journal (*Lancet* 46a and b).

By courtesy of Dr. Spies and Messrs. Lederle Laboraies Inc. we have received a small quantity of synthetic ic acid, and have treated nine patients suffering from galoblastic anæmia. For this initial investigation we se six cases of classical addisonian pernicious anæmia, h typical megaloblastic bone-marrow and histamine-t achlorhydria, but with no neurological signs and preceding history of diarrhœa or dietary deficiency. ese six patients were given folic acid in varying amounts mouth or by injection. The object of this part of the estigation was to confirm the hæmopoietic activity of ic acid, as recorded by Spies (1946), and to assess sage. The other three cases were examples of refractory galoblastic anæmia of the type described by Davis d Davidson (1944) which failed to respond to parenteral er therapy but responded to proteolysed liver given mouth.

During the present investigation, our patients received normal ward diet, but no liver was included in the meals. similar diet has been given by us to many cases of rnicious anæmia, and of refractory megaloblastic æmia, without producing any change in the blood cture. In all cases, a control period of at least a fortght was instituted before the commencement of folic id therapy to ensure that spontaneous remission was ot taking place.

ADDISONIAN PERNICIOUS ANÆMIA

CASE 1.—A man, aged 72, with typical addisonian pernicious æmia, under treatment for 4 years. He had responded tisfactorily to 'Anahæmin,' but some months before lmission his doctor had stopped treatment with parenteral er on account of general and local reactions. At the comencement of folic acid therapy his hæmatological findings ere Hb 38% (5·2 g. per 100 c.cm.); red cells 1 250,000 per mm.; white cells 4400 per c.mm.; P.C.V. 17·5%; M.C.V. 10·0 c.μ; M.C.H.C. 29·7%; reticulocytes <1%; C.I. 1·5.

The patient was tested with folic acid and anahæmin 01 c.cm. intracutaneously. A marked local reaction occurred the site where the liver was injected, but no reaction curred from the folic acid. Accordingly folic acid 20 mg. as given intramuscularly on the 1st and 2nd day of treatent; no local or general reaction occurred. Folic acid 0 mg. was given by mouth daily from the 3rd to the 20th ay of treatment. Table I shows that there was a very atisfactory rise in reticulocytes, red cells, and hæmoglobin, hich was up to the standards demanded by the United tates Pharmacopœia Anti-anemia Preparations Advisory oard (hereafter referred to as the *U.S.P.* standard). After lic acid treatment was stopped, the red cells and hæmoglobin ontinued to rise for a further 21 days, without additional herapy. Owing to the limited supply of folic acid, treatent with anahæmin was started on the 41st day, after reliminary desensitisation, and by the 81st day the bloodount and blood picture had been restored almost to normal.

CASE 2.—A man, aged 37, with typical addisonian pernicious nemia. He was first treated with liver injections 18 months efore the present investigation and improved greatly as a esult: at that time he was in the Services overseas; he had ad no tropical disease. He was discharged from the Army n account of ill health, and had had no anti-anæmic therapy for 9 months before he was referred to us. At the commencement of folic acid therapy his hæmatological findings were: Hb 52% (7·2 g. per 100 c.cm.); red cells 2,050,000 per c.mm.; white cells 3400 per c.mm.; P.C.V. 22·0%; M.C.V. 107·3 c.μ; M.C.H.C. 32·7%; reticulocytes <1%; C.I. 1·3.

The patient was given folic acid 10 mg. by mouth daily *for 20 days. Table I shows that this resulted in a good hæmato*poietic response which, however, did not reach the *U.S.P.* standard; but by the 28th day the erythrocyte increase was satisfactory on this basis. The red cells continued to increase for a further 23 days after the cessation of folic acid therapy, and no rise occurred during the ensuing 27 days. It is to be noted that although the hæmoglobin was 100%, the colour-index was still above unity.

CASE 3.—A man, aged 52, with typical addisonian pernicious anæmia. He had suffered from weakness and breathlessness for a year, but these symptoms had become much worse during the four months prior to admission to hospital. He had never previously been treated with liver. At the commencement of folic acid therapy his hæmatological findings were Hb 50%; red cells 1,870,000 per c.mm.; P.C.V. 23·5%; M.C.V. 125·7 c.μ; M.C.H.C. 29·4%; reticulocytes <1%; C.I. 1·3. He was given folic acid 10 mg. daily by mouth. From table I it will be seen that this produced an increase of 1,270,000 red cells and 26% Hb in 14 days—which is fully up to the *U.S.P.* standard. Owing to shortage of beds, the patient was treated as an outpatient for the first 7 days, and hence the peak of the reticulocyte rise was not established.

CASE 4.—A man, aged 53, with typical addisonian pernicious anæmia. He had suffered from weakness and breathlessness for 6 weeks before admission. No anti-anæmic therapy had been given before admission to hospital. At the commencement of folic acid therapy his hæmatological findings were: Hb 36% (5·0 g. per 100 c.cm.); red cells 1,270,000 per c.mm.; white cells 3800 per c.mm.; P.C.V. 14·5%; M.C.V. 114·2 c.μ; M.C.H.C. 34·5%; reticulocytes <1%; C.I. 1·4.

The patient was given folic acid 5 mg. daily by mouth for 68 days. Table I shows that he gained 36% Hb and 1,780,000 red cells per c.mm. in 21 days—a rise which conforms to the *U.S.P.* standard. The reticulocyte rise and the rate of regeneration over the first 14 days of treatment were, however, below this standard. By the 57th day of treatment the hæmoglobin had reached 100%, but the colour-index was still above unity, and the M.C.V. was 102·4 c.μ.

CASE 5.—A woman, aged 38, with typical addisonian pernicious anæmia, who had never had liver therapy. She had suffered from weakness and breathlessness for two years, but these symptoms had become much more marked during the two months prior to admission to hospital. Partial thyroidectomy for thyrotoxicosis had been carried out six years previously, with remission of all symptoms and signs other than exophthalmos. At the commencement of folic acid treatment her hæmatological findings were: Hb 28%; red cells 970,000 per c.mm.; white cells 1200 per c.mm.; P.C.V. 11·5%; M.C.V. 118·6 c.μ; M.C.H.C. 33·9%; reticulocytes 2·4%; C.I. 1·44.

She was given folic acid 200 mg. intramuscularly in the first twenty-four hours. Table I shows that this resulted in a sharp rise of reticulocytes and an increase of more than one million red cells and 20% hæmoglobin in 11 days—a result which fully satisfies the *U.S.P.* standard optimal rise. The effect of this initial injection had finished by the 14th day; so a second injection of 100 mg. was given. This resulted in the reticulocytes rising to 16% on the 4th day after injection, and a gain of half a million red cells and 14% hæmoglobin in six days.

CASE 6.—A woman, aged 79, with typical addisonian pernicious anæmia. She complained of increasing weakness and breathlessness for six months. Two years previously she had been treated for pernicious anæmia, but had had no liver by mouth or by injection for the past year. At the commencement of folic acid treatment her hæmatological findings were: Hb 26%; red cells 1,080,000 per c.mm.; white cells 2000 per c.mm.; reticulocytes <1%; C.I. 1·2.

The patient was given a single dose of folic acid 400 mg. by mouth. Table I shows that the response was truly dramatic, particularly in view of the patient's age. The reticulocytes started to increase rapidly on the 3rd day, and reached the high figure of 42% on the 5th day. Fourteen days after the administration of the single large dose of folic

Cases with raised blood-pressure gave normal readings from one to three weeks after considerable improvement or disappearance of the symptoms.

DISCUSSION

The painful-feet syndrome developed among British and Australian prisoners-of-war in Japanese hands six months after they had been on a diet low in vitamin-B complex and first-class protein but adequate in total calories. Fresh cases ceased to appear in any number, and the patients gradually recovered after a few months, when there was an all-round improvement in the diet, with an increase in protein and the vitamin-B complex, particularly vitamin B_1 and nicotinic acid. The syndrome had almost disappeared before there was any increase in the riboflavine intake. The peak incidence of painful feet occurred at a time when fresh cases of recognised vitamin-B_1 deficiency were relatively few and the vitamin-B_1 non-fat-calorie ratio was above the critical level of 0·3 (Williams and Spies 1938).

Crystalline vitamin B_1 given intravenously in a few cases produced no improvement. The intravenous *administration of the diethylamide of nicotinic acid* brought about relief or much improvement in 68·8% of cases in which it was used. This substance has no pharmacological vasodilator effect, as has nicotinic acid. No other pure vitamin of the B complex was available for therapeutic trial. No definite conclusions can be drawn from the results of treatment with marmite, green gram, and rice polishings, as there were no adequate controls; the only controls were 9 patients who received no treatment except two weeks' rest, of whom 2 improved considerably.

The beneficial effects of a diet or of dietary supplements containing adequate amounts of vitamin-B complex point to a B-complex deficiency. The nicamide observations suggest a deficiency of nicotinic acid as an important factor. But, at a later date of imprisonment, when the nicotinic-acid content of the diet again fell to, and remained at a level as low as, that at which the initial outbreak developed, there was no recurrence of these cases in any great number. During this later period, in contrast to the earlier, the riboflavine content of the diet was adequate. A simultaneous deficiency of nicotinic acid and riboflavine may therefore be necessary for the production of the syndrome. The evidence obtainable in the circumstances in which the syndrome was observed does not justify any more definite conclusion.

Pain.—The patients' descriptions of the pain do not throw much light on the mechanism of its production. It differs distinctly from that of causalgia, pink disease, intermittent claudication, erythromelalgia (Brown 1932, Lewis 1936), pseudo-erythromelalgia (Craig and Horton 1938), and asthenia crurum dolorosa (Ekbom 1944). The stabbing pains of the painful-feet syndrome are reminiscent of tabetic lightning pains, but are felt as longitudinal not as transverse stabs, and only below the knees. There is a closer resemblance between the combined aching and stabbing pains of the syndrome and the pain of peripheral neuritis in its earlier irritative stages, but in peripheral neuritis exercise and pressure usually aggravate the pain, and muscular tenderness is present. The closest resemblance is afforded by the immersion-foot syndrome (Ungley et al. 1945), in the hyperæmic stage of which a diffuse severe burning or throbbing pain is felt in feet and legs; about 7–10 days after rescue shooting or stabbing pains are superadded, in bursts like machine-gun fire and radiating from the centre of the foot. They are relieved by cold but aggravated by heat and by exercise; and they are accompanied by circulatory changes and objective neurological signs not seen in the painful-feet syndrome. The excessive sweating seen in some severe cases of painful feet resembles that described in the later stages of immersion foot.

Peripheral nerve damage is demonstrable c and pathologically in immersion foot. The resembl between the pain of painful feet and of immersi and peripheral neuritis suggests that the fo may be produced by some dysfunction of peri nerve-fibres or nerve-endings which does not pr to a stage where clinical evidence of nerve dam found. It seems unlikely that the pain is due to c tory changes in the feet, since it does not resemb pain of known disorders of the blood-vessels, and was no clinical evidence of local vascular dis The mechanism by which the pain is produced is th obscure; a metabolic disturbance of nerve-fibr nerve-endings, due to vitamin deficiency, is the attractive hypothesis.

Exaggerated Reflexes.—The significance of th difficult to assess. They developed in only 23% o cases. Their presence in the arms in many pat whose pain was confined to the feet and legs against any explanation based on hyper afferent nerve-endings. In the great majority of c they were not accompanied by any other sign of pyramidal-tract lesion; the abdominal and cremas reflexes, for example, were active, and the pl responses were flexor except in a few cases where feet were hypersensitive and equivocal responses obtained. It seems likely that the exaggerat of reflexes, which developed mostly in the more cases, may have been an effect of protracted pain and of sleep. On the other hand, when the incidence o feet was at its height, there occurred in the camp cases of frank spastic paraplegia and a few of quadr of obscure ætiology. Some of these began as painful with exaggerated reflexes, and later developed cl signs of upper motor neurone damage. It is possible, fore, that exaggerated reflexes in painful feet sig minimal and reversible degree of damage to the nervous system, due presumably to dietary deficie

Hypertension.—There is no evidence to show w the hypertension observed in 51 out of 180 cases quately examined, is attributable to a specific distur of blood-pressure regulation or is a general effect of long-continued pain and sleeplessness with which it always associated. In all cases except one the b pressure fell with recovery to within normal li In cases where pain was promptly relieved by nic the fall was not abrupt but took place gradually or two weeks. In the single case where hyperten persisted, it was still present after three years and regarded as essential hypertension.

SUMMARY

A syndrome of which the chief features were a and stabbing pains in the feet was observed in pris of-war in Singapore at a time when their diet was de in protein and the vitamin-B complex. Hyperten and exaggerated tendon reflexes were added featur some cases. Observations on 500 patients are record

The diet records, and the beneficial effect of treatm with nikethamide (the diethylamide of *nicotinic* a point to a deficiency of nicotinic acid, perhaps conjunction with riboflavine deficiency, as a factor in the production of the syndrome.

I wish to thank General A. G. Biggam for permissi publish this paper; Dr. R. C. Burgess, who was respo for the diet calculations; and Prof. R. S. Aitken for and criticism in the preparation of the article.

rise, an alteration of his bone-marrow from a megalo- tic to a normoblastic state, and a rise in erythrocytes which satisfactory for the first 8 days but thereafter failed to rove with this therapy (table III). Although the stool ridine was negative, the M.C.H.C. was only 26·3% on the h day. Accordingly ferrous sulphate was given for 14 days hout result. The patient was then given proteolysed liver ablespoonful t.i.d. for 14 days. This resulted in an increase ialf a million red cells per c.mm. in 11 days, but thereafter further improvement took place.

ASE 9.—A man, aged 62, had been under treatment for ractory megaloblastic anæmia since 1942. He showed no ponse to anahæmin, but on the recommendation of one of (L. S. P. D.) proteolysed liver was tried in January, 1945. e results of this treatment were satisfactory, the bone-marrow inging from a megaloblastic to a normoblastic state and red cells rising from 1·93 to 3·44 million over a period of days, with a reticulocyte peak of 11·0%. The patient was able to obtain proteolysed liver after May, 1945, and had no rapy other than iron and cod-liver oil up to the time of readmission to hospital in June, 1946. Clinical examina- n revealed that the liver was two finger-breadths enlarged palpation; the spleen was not palpable, and no glandular largement was found. The ankle reflexes could not be cited, the knee-jerks were weak, and there was an tensor plantar response on the right side, the left being ubtful. The patient was underweight; there was no history diarrhœa, no evidence of glossitis, and the dietetic history s satisfactory. A test-meal showed that there was hista- ne-fast achlorhydria. At the beginning of the present estigation the blood figures were: Hb 46% (6·3 g. per 0 c.cm.); red cells 1,700,000 per c.mm.; white cells 6200 r c.mm.; P.C.V. 22·0%; P.C.V. 129·4 c.µ; M.C.H.C. 28·6%; ticulocytes 1%; C.I. 1·4.

This patient was first given 4 c.cm. of anahæmin—twice much as our experience has shown to be adequate to roduce a maximal response in addisonian pernicious anæmia. his resulted in a slight rise in reticulocytes and an unsustained se in red cells. The bone-marrow, however, remained egaloblastic. Folic acid therapy was then begun, and a cond submaximal rise in reticulocytes occurred (table IV). his was followed by a rapid red-cell rise and change in the one-marrow to the normoblastic state. Treatment with folic id for 28 days produced a gain of approximately two illion erythrocytes and 34% hæmoglobin. Continued treat- ent, however, failed to increase the blood-count, and e blood picture remained macrocytic. Treatment with roteolysed liver is now being given.

Therapy.—20 mg. folic acid by mouth on 1st to 36th days. errous sulphate gr. vi t.i.d. on 21st to 35th days. Proteolysed ver one tablespoonful t.i.d. on 36th to 50th days.

DISCUSSION

This short series includes six cases of addisonian ernicious anæmia, of which four were treated with olic acid daily by mouth in doses ranging from 5 mg. to 0 mg.: two received a single large dose by the parenteral nd oral route respectively. Of the cases receiving daily ral treatment, only case 1, who received 20 mg. daily, ad a reticulocyte response and red-cell rise completely p to the standard demanded by the *U.S.P.* Board. ases 2 and 3, who received 10 mg. daily by mouth, eached the standard at 28 days and 14 days respectively. he reticulocyte rises, however, were suboptimal. With regard to case 4, who received 5 mg. daily, the red-cell rise over 21 days conformed to the *U.S.P.* standard, but the reticulocyte rise was suboptimal. In all six cases the bone-marrow was transformed from a megaloblastic to a normoblastic state. The clinical state of the patients improved coincidentally with the blood.

Therapy.—1st day 2 c.cm. anahæmin, 2nd day 2 c.cm. anahæmin; 20 mg. folic acid by mouth on 17th to 49th days.

The variations in response of individual cases of pernicious anæmia, with similar blood levels, to parenteral treatment with a standard amount of a potent preparation of liver is recognised by all hæmatologists, and is the principal factor in causing great difficulty in the assessment of potency and dosage. Hence it would be unwise to define the optimal daily dose of folic acid until a much larger series of cases has been treated. Our observations suggest that the therapeutic daily dose by mouth is between 5 mg. and 20 mg. At the time of writing, it would be safer not to reduce the daily dose below 20 mg. in the treatment of pernicious anæmia—an amount found to be satisfactory by Wilkinson et al. (1946).

Attention is drawn to the excellent response which resulted from a single large dose of folic acid given by mouth or parenterally. If results similar to those produced in case 6, who received a single dose of 400 mg. orally, can be obtained regularly, the simplest and most effective method of treatment may prove to be an initial large dose followed at weekly or fortnightly intervals by doses of 50–100 mg.

Most reports have been of treatment with folic acid over relatively short periods, presumably because of the small supply. Published accounts do not clearly indicate that folic acid by itself can regularly restore the blood picture to normal in pernicious anæmia, but we have had private reports from the United States that this has been accomplished. The problem of maintenance therapy has yet to be settled.

With regard to the three cases of refractory megaloblastic anæmia, the following observations appear to be justified.

1. Parenteral injection of a potent purified liver extract was ineffective, while folic acid, in each case, produced a rise in reticulocytes, red cells, and hæmoglobin, and transformed the bone-marrow from the megaloblastic to the normoblastic state. In no instance, however, was folic acid alone able to restore the blood picture to normal.
2. Proteolysed liver by mouth was able to restore the blood picture to normal in case 7, after the red-cell count had ceased to rise with adequate administration of folic acid. In case 8, proteolysed liver also caused a further rise in red cells subsequent to folic acid therapy, but did not restore the blood to normal. Treatment with proteolysed liver has just been begun in case 9.

* Folic acid 10 mg. was given daily by mouth from the 71st day, and this produced a further rise of red-cell count to 5·05 million o the 91st day.

acid, the red cells had increased by two million per c.mm., and the hæmoglobin by 42%. No further rise occurred by the 18th day, so folic acid 100 mg. was given by mouth on the 21st day. The red-cell increase reported above far exceeds the *U.S.P.* standard.

REFRACTORY MEGALOBLASTIC ANÆMIA

CASE 7.—A woman, aged 37, first admitted to hospital in March, 1944, when she was 5 months pregnant. Her hæmoglobin was then 56% and red cells 2,050,000 per c.mm. The bone-marrow was megaloblastic. A test-meal showed the presence of free hydrochloric acid. A diagnosis of pernicious anæmia of pregnancy was made. She failed entirely to respond to 4 c.cm. of anahæmin given intramuscularly, but responded to proteolysed liver, an increase of red cells of one million per c.mm. occurring in 20 days. The patient was then discharged from hospital, but owing to difficulty in obtaining proteolysed liver she did not continue treatment. She was readmitted in April, 1946, with a history of weakness and of intermittent diarrhœa of a fatty type; a fat-balance test carried out according to the method of Cooke et al. (1946) showed the percentage absorption to be 75%. A test-meal again showed the presence of free hydrochloric acid, and the patient was now thought to be suffering from idiopathic steatorrhœa. She had never been abroad, and the dietetic history was normal. No anti-anæmic treatment had been given for 18 months before the commencement of folic acid therapy as described below. During a control period of 14 days, the reticulocyte count ranged from 2% to 3·5%, but the erythrocyte and hæmoglobin levels remained stationary. At the start of folic acid therapy her blood findings were as follows: Hb 40% (5·5 g. per 100 c.cm.); red cells 1,370,000 per c.mm.; white cells 7800 per c.mm.; P.C.V. 19·0%; M.C.V. 138·7 c.μ; M.C.H.C. 28·9%; reticulocytes 3·5%; C.I. 1·5.

The reticulocyte response and the rise in red cells over a therapeutic period of 14, 21, and 28 days reached the standards demanded by the *U.S.P.* Board, although the patient was suffering from idiopathic steatorrhœa and not from addisonian pernicious anæmia (table II). Despite continued folic acid therapy, 20 mg. daily, no further rise in red cells occurred during the next 20 days. The M.C.H.C. on the 36th day was 27·2%, and, in view of this evidence of iron deficiency, ferrous sulphate was then added to the treatment. Ten days' treatment with iron produced a small rise in the hæmoglobin and no change in the red-cell count. Accordingly, intensive therapy with anahæmin was begun, treatment with folic acid and iron being continued *simultaneously*. Seventeen days after the commencement of parenteral liver therapy the level of hæmoglobin and red cells remained unchanged. Treatment with proteolysed liver was then begun, 1 tablespoonful t.i.d. being given. An increase of one million red cells and 14% hæmoglobin occurred in 13 days, with the restoration of the blood picture to normal.

CASE 8.—A man aged 61. Six weeks before this patient came under our charge he had been diagnosed as having pernicious anæmia, and during the month preceding the commencement of folic acid therapy he had been given 24 c.cm. of anahæmin. There was no response to this therapy; th blood figures continued to fall, and the bone-marrow remain megaloblastic. The patient gave a 2 years' history of weakness and breathlessness. He said that he suffered from hæmor rhoids, which had bled intermittently during the preced 6 years. No loss of blood was evident after admission t hospital, and the stool benzidine test was persistent negative. The dietetic history was normal, and there was diarrhœa. There were no abnormal neurological signs; th liver and spleen were not palpable, and there was no abnor glandular enlargement. There was no history of hæmatem and no visible enlargement of veins on the abdom wall. There was no albuminuria. It is noteworthy that th patient's daughter died in our wards a year ago with a seve refractory megaloblastic anæmia and was found at autops. to have cirrhosis of the liver. In view of this family histor liver-function tests were performed on our patient. Th serum bilirubin was 0·65 mg. per 100 c.cm.; the blood ch terol was 167 mg. per 100 c.cm.; and the cephalin cholest test was negative. Serum alkaline phosphatase was 7 u per 100 ml.; serum albumin 3·06 per 100 c.cm.; ser globulin 2·15 g. per 100 c.cm. The lævulose-tolerance te and hippuric-acid test were both normal. In short neit clinical examination nor laboratory tests demonstrated th presence of hepatic dysfunction. No adequate explanat for the low serum albumin was found. At the commence of folic acid therapy the blood figures were: Hb [illegible] (3·9 g. per 100 c.cm.); red cells 950,000 per c.mm.; whi cells 5200 per c.mm.; P.C.V. 13·0%; M.C.V. 136·8 c.μ; M.C.H.C. 30·0%; reticulocytes 2·2%; C.I. 1·5.

This patient, who showed no response to a very large dose of anahæmin, responded to folic acid therapy with a retic

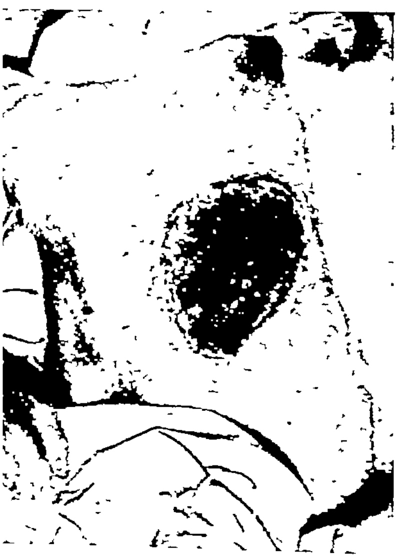
itary history, but he said that he had served all over the ld but had never had dysentery. The beginning of the ss he attributed to a "strain," the result of lifting heavy ls, which caused a "lump" to appear in the left lower omen. This was associated with diarrhœa, tenesmus, piles.

Ie was admitted to hospital, where his stools were examined hout anything being found to explain the diarrhœa. He was told that he had cancer of the bowel, and left iliac colostomy was performed, presumably preparatory to removal of the "growth."

After the operation a large infected area developed round the colostomy, and it was only by diathermy excision that further spread was prevented.

The patient had been discharged from the Service and had been sent to Queen ry's Hospital for further investigation and treatment. it was less than six months since his operation and he s anxious to go home to help with the harvest, he was charged and instructed to return later for closure of ostomy.



œbiasis of skin following closure of colostomy

He was later readmitted to Queen Mary's Hospital, when was in good health. There was no blood or mucus in the ols. For four days before operation he was given succinyl phathiazole tablets to sterilise, as far as possible, the itents of the large intestine.

At operation the colostomy was dissected free. In spite extensive scarring of the abdominal wall, the bowel was bilised without much difficulty and without the peritoneal ity being entered. Continuity of the bowel was reablished, and the layers of the wound were drawn together er a small drainage-tube.

The wound progressed well for three days but then became itely inflamed and broke down completely. The sutures the bowel also gave way, with re-establishment of the ostomy.

During the next four weeks the infected area continued to ead in spite of every form of treatment, local and general. e inflamed area extended almost from the iliac crest to the tal margin and consisted of foul sloughing tissue (see ire). The patient's general condition was rapidly erlorating.

Reviewing the case, the possibility of amœbiasis occurred me, even though examination of the stools elsewhere had parently proved negative. A fresh specimen was examined Dr. Mackenzie Douglas, who reported the presence of nerous *E. histolyticæ*.

The further care of the patient was then undertaken by J. G. Willmore, to whom I am indebted for an account of treatment. Intramuscular emetine gr. 1 was given daily twelve days, and 'Diodoquin' 2 tablets by mouth ce daily for ten days. The local area was kept as dry possible, and for this reason the bowel was not irrigated h 'Quinoxyl'; the sloughing wound was dusted vily with a powder consisting of equal parts of ium penicillin and succinyl sulphathiazole and covered h tulle-gras.

he stools rapidly became clear of amœbæ, the man's general dition improved rapidly, and a striking feature was the ppearance of the agonising pain in the wound and its d healing.

DISCUSSION

This was one of our earlier cases and occurred before I had come to consider that a colostomy without any lesion to explain it was almost pathognomonic of amœbiasis. It was thought advisable to publish the case in view of the possibility of surgeons in different parts of the country having to deal with colostomies of this type—i.e., where investigation proves negative and amœbæ are not found in the fæces.

Amœbiasis of the skin was originally described in 1892 by Nasse (cited by Manson-Bahr 1938), who recorded a case of ruptured liver abscess with invasion of the skin. Nasse recognised living entamœbæ not only in the liver pus but also in the skin at the advancing edges of ulceration.

Hsu (cited by Manson-Bahr 1938), in China in 1937, described circum-anal ulcerations, fistulæ, and warts, due to dysentery amœbæ. He demonstrated the organism in sections, in erosions of the cervix, and in urethral ulcers in the male.

Manson-Bahr (1938) described a case similar to the one recorded above, in which the parietes in the vicinity of the colostomy and abdominal wall were involved. He emphasises the fact that this peculiar gangrene, with its colour, method of spread, and punched-out margins of ulceration, cannot be forgotten or confused with any other form of gangrene or ulceration of the skin. He further emphasises the importance of microscopical sections of the gangrenous skin, where the amœbæ will be found, even though they may not have been found in the stools.

Gabriel (cited by Manson-Bahr 1938) reported a case in an ex-soldier who had served in India fifteen years previously. Though the patient had never had clinical dysentery, *E. histolytica* cysts were present in the fæces. The lower part of the rectum, the pelvic floor, and the perineal tissues had been destroyed. Response to emetine therapy was remarkable.

It may be as well to call attention to the converse of the error described above—i.e., where patients with carcinoma of the rectum have been treated for dysentery. I have seen two such cases. In each the mistake was due to the omission of digital examination of the rectum. Both patients had been sigmoidoscoped and examined with X rays and barium enema. In both the carcinoma was situated low down in the rectum; in one it involved the side wall, and in the other the growth completely encircled the bowel. In the first case the sigmoidoscope was passed beyond the ulcer without suspicion, whereas in the second it was evidently passed through and beyond the growth before observation began. Both patients had been treated elsewhere for amœbic dysentery and had been referred for operation for hæmorrhoids.

The barium enema does not help much in the diagnosis of neoplastic conditions of the rectum, particularly those situated low down, for the delineation of a filling defect with barium does not properly begin until the pelvirectal junction is reached. It is equally possible to miss a carcinoma of the rectum with the sigmoidoscope, and this emphasises the fact that the first internal examination should always be with the finger. The patient should be requested to strain down so that an ulcer, which at first may not be palpable, may come within the ambit of the examining finger.

I am indebted to Sir Walter Haward, D.M.S. Ministry of Pensions, and Major-General Brooke Purdon, medical superintendent, Queen Mary's Hospital, Roehampton, for permission to publish this article.

It is of interest to note that cases 7 and 9 had previously responded to proteolysed liver. Since megaloblastic anæmias, refractory to anahæmin, will respond to both proteolysed liver and folic acid, it might be postulated that folic acid is the active principle in proteolysed liver. The data obtained in cases 7 and 8, however, indicate that a refractory megaloblastic anæmia can respond to proteolysed liver after folic acid has ceased to be effective. This would suggest that in liver and proteolysed liver there exists some as yet undiscovered anti-anæmic principle additional to the specific anti-anæmic factor in anahæmin, and to folic acid.

SUMMARY

An account is given of the response of six cases of addisonian pernicious anæmia and three cases of refractory megaloblastic anæmia to folic acid.

In all cases the bone-marrow was transformed from a megaloblastic to a normoblastic state.

The effective daily dose of folic acid given by mouth to cases of pernicious anæmia in the relapse stage varies widely in different patients. The suggested dose is 20 mg. daily.

Three cases of megaloblastic anæmia refractory to 'Anahæmin' responded to folic acid which was, however, unable to restore the blood to normal.

The relationship of folic acid to proteolysed liver is discussed.

CONFUSION OF AMŒBOMA WITH CARCINOMA

MICHAEL J. SMYTH
M.Ch. N.U.I., F.R.C.S.
SURGEON, QUEEN MARY'S HOSPITAL, ROEHAMPTON

THE many abdominal cases admitted to Queen Mary's Hospital, Roehampton, during the later years of the war 1939–45 included some in which left iliac colostomy had been performed for no apparent reason. The patients had not sustained any wounds affecting the pelvic colon or the rectum. Digital examination of the rectum, sigmoidoscopy, and barium enema did not reveal any lesion which would have justified operation. In some cases the operation had been advised for neoplasm of the rectum, and in others a definite diagnosis of carcinoma had been made, yet no trace of any new growth could be found. At first I naturally thought that a mistake had been made, that overwork, perhaps the heat and burden of the desert, had been responsible for a "phantom tumour"; but, as other cases followed, and as the operation had been advised, and in some instances carried out, by well-known surgeons, it was clear that there must have been some compelling reason for operation. The answer was not far to seek, though at first it was not obvious.

In tropical regions where amœbiasis is endemic *Entamœba histolytica* may cause in the large intestine a granulomatous condition which is often mistaken for carcinoma. A good example is cited by Ogilvie (1945). A factor common to the patients mentioned above was that they had all had amœbic dysentery, and all except one had been treated with emetine. The logical conclusion was that the colostomy had been performed for an "amœboma" of the rectum or of the pelvic colon, and that the operation, with or without emetine, had brought about the disappearance of the tumour.

Manson-Bahr (1945) has emphasised that amœbiasis is more widespread than is commonly realised, and that not only can it be contracted without causing pronounced symptoms, but also it may lie dormant for years before declaring itself. He has described (personal communication) the case of an officer who contracted the disease at the age of 2 years and developed a liver abscess at the age of 28, with no symptoms during the intervening years. A similar case was seen by one of my colleagues, *Dr. J. G. Willmore. Here*, a retired warrant officer who had contracted dysentery in the Burmese war 1885, developed a large liver abscess in 1922, [illegible] signs of illness and without having left *England* [illegible] the intervening years.

It is important that the prevalence of amœbiasis should be recognised, and that surgeons should be [illegible] to the possibility of amœbic granuloma simulating carcinoma. I have no doubt that in amœboma of the rectum colostomy is helpful rather than otherwise, but the [illegible] is that large-scale operations on the bowel may [illegible] performed without any attempt at differential diagnosis. Some even question the advisability of colostomy [illegible] such cases and look upon the operation as unnecessary and somewhat drastic. It is easy to be wise after [illegible] event, when the nature of the tumour is realised, but [illegible] man on the spot is often in the best position to judge and the operation may have been the best for the patient in the circumstances. One might go further and [illegible] that, whatever the diagnosis, colostomy in the presence of acute or subacute obstruction was the only correct surgical procedure and, as a temporary expedient, undoubtedly saved life.

Radical surgery, such as resection of the colon [illegible] excision of the rectum, is much more serious. In three cases reported by Gunn and Howard (cited by Howells 1946) the preoperative diagnoses were carcinoma [illegible] transverse colon, carcinoma of cæcum, and carcinoma of colon. Two of the patients died as a direct result [illegible] operation. Yeomans (*cited by Howells 1946*) *emphasises the almost invariably fatal outcome* of radical surgery without anti-amœbic treatment.

If a tumour of the colon or of the rectum is discovered in a person who has served in the East, it would be wise to regard it as an amœboma rather than a carcinoma until thorough pathological examination has proved otherwise. In amœboma of the colon special care [illegible] repeated examination of the stools may be necessary before *E. histolytica* is demonstrated. With accessible tumours, like those of the rectum, a biopsy should not be omitted, for the specimen may not only help to distinguish a neoplasm from an inflammatory condition *but also provide evidence of E. histolytica* cysts. Failing the services of a pathologist experienced in tropical protozoology, a course of emetine should precede any attempt at radical surgery.

Occasionally amœboma and carcinoma may coexist. Morgan (1946) reported the case of a young R.A.F. officer with a swelling in the right *iliac fossa*. Investigation proved that he had contracted amœbic dysentery and appropriate treatment led to almost complete disappearance of the tumour. The patient reported [illegible] hospital later, when it was found that the swelling had recurred; and, owing to the failure of further treatment operation was decided on. On removal of the cæcum the tumour proved to be carcinomatous.

AMŒBIASIS OF SKIN AND SUBCUTANEOUS TISSUE

I wish to draw attention to a condition which may affect the skin and underlying tissues and may readily develop after colostomy performed for such cases, when amœbiasis is not suspected.

A colour-sergeant of the Royal Marines, aged 57, was admitted to Queen Mary's Hospital, Roehampton, with diagnosis of carcinoma of rectum. There was little [illegible] t but a metabolic disturbance, and it is thought in gout uric acid probably circulates in an abnormal . This explains why the kidneys cannot eliminate uric acid, which consequently collects in the blood. ratosis, as opposed to hyperuricæmia, is absolutely ined to gout and is pathognomonic of it. Though osis probably does not occur in the absence of hyper- æmia, the latter may exist for prolonged periods iout inducing the occurrence of uratosis—i.e., gout. s thought that in gout the uric-acid salts which have umulated in the blood alter from a soluble to a less ible state, the blood becomes supersaturated, and tes are suddenly deposited from the supersaturated tion. Inflammation is excited mechanically by the osition of urate crystals in the affected tissues, and a ty paroxysm results.

n the present case the attack of gout came on in a ient who, except for age and sex, did not show the al predisposing factors cited in gout, such as heredity l habitual excesses in food and drink. This case thus fers from that reported by Vining and Thomson (1934), which there was a family history of gout. They sidered that the obvious explanation in their case s that in the leukæmic state there were present large ntities of uric acid from the breakdown of immature ite cells which, in a subject carrying a latent tendency gout, led to uratosis. The attack of gout in my patient s apparently produced as a direct result of the greatly reased uric-acid content of the blood resulting from rapid destruction of white blood corpuscles. After first dose of 100 r the white-cell count was reduced in a days from 354,000 to 225,000 per c.mm., and it was this time that the attack of gout developed. It there- e seems that acute gout can, though apparently very rely, result purely from the increased amount of uric id in the blood which occurs in leukæmia.

TUBERCULOUS ABSCESS FOLLOWING INTRAMUSCULAR PENICILLIN

REPORT OF A CASE

DENIS EBRILL
M.S. Lond., F.R.C.S.
SIDENT ASSISTANT SURGEON

STEPHEN D. ELEK
M.D. Lond., D.P.H., D.C.P.
ASSISTANT BACTERIOLOGIST

ST. GEORGE'S HOSPITAL, LONDON

So far as we know, tuberculous infection at the site of nicillin injections has not been described. Abscesses erile on routine examination are not infrequent; but ey are not always examined for tubercle bacilli. We ve observed a case in which there is reason to believe at penicillin administration was responsible for a berculous abscess. Theoretically, direct inoculation the time of injection appears to be possible. If this is —and the case to be described appears to bear it out— is an indication for more stringent precautions in the ministration of penicillin.

A boy, aged 11 years, with no relevant previous medical story, was admitted on July 24, 1945, with a large painful scess in the right axilla which had been present for about week. Two days after admission the abscess had become ft and was opened. The pus gave a pure growth of *Staph. ureus.* On the 30th a continuous intramuscular penicillin ip was set up. The initial site of injection was the outer pect of the upper third of the left thigh. During the first enty-four hours patient complained of much discomfort the site of injection, whereupon the drip was discontinued d a fresh one put up in a similar site in the right leg. The nicillin was discontinued on August 3, by which time he had d 500,000 units. On the 22nd patient was discharged, with his wound healed and no evidence of any residual suppuration.

On Nov. 30—i.e., some three months later—he again attended hospital, complaining of a painful swelling in the left thigh near the site of his first penicillin injection. A spherical fluctuant swelling, about 3 inches in diameter, was found on the lateral aspect of the upper third of his left thigh. There was no evidence of skin involvement, and the swelling was only slightly tender. A chronic abscess seemed the most likely diagnosis, infection by one of the common penicillin-resistant contaminants being postulated. He was admitted to hospital three days later, the swelling having increased in size during this period. On Dec. 5 the abscess was explored through a small incision and about 8 oz. of thin yellowish fluid and some fibrinous clots were evacuated. The bacteriological report on the pus was as follows: "Routine cultures sterile. Morphological *Myco. tuberculosis* present in large numbers in the direct smear." Later the acid-fast bacilli were confirmed to be *Myco. tuberculosis* by culture and by guineapig inoculation.

The abscess did not heal, and exuberant granulation tissue appeared in the wound. Histological examination of this showed typical tuberculous granulation tissue. Radiography of his chest, spine, and legs showed no abnormality. At this time his Mantoux reaction was positive in 1 in 10,000 O.T.

On Jan. 7, 1946, an attempt was made to excise the tuberculous area completely. A large diffuse area of necrotic tissue was found extending superficial and deep to the fascia lata and tracking in the intermuscular planes almost as far as the shaft of the femur. At no point could the bone be felt to be directly involved. The pathological tissue was excised. The wound was closed completely, apart from a small drain at its lower extremity, which was removed on the second day. Complete healing was eventually obtained.

DISCUSSION

The history of the case suggests that a hæmatoma formed at the site of the first penicillin injection. This would explain the severe pain noticed at the time. Human blood is an excellent medium for the growth of tubercle bacilli, and early evidence of growth can be observed in two or three days.[1] We have observed that the addition of penicillin to laked human blood appears to improve the growth of tubercle bacilli. One of us has found in in-vitro experiments that this is especially so when the concentration of penicillin in the blood is low. The optimal concentration appears to be about 20 units per c.cm. When the concentration of penicillin is very high, this adjuvant effect disappears. Furthermore, by keeping the hæmatoma sterile, penicillin would prevent it from being overgrown with contaminants which would interfere with the growth of tubercle bacilli.

Regarding the source of the tuberculous infection, the most obvious and indeed the most likely solution is that it was introduced at the time of the injection. Tubercle bacilli might have gained access to the penicillin powder, the diluted penicillin solution, or the apparatus or needle used. The infection could have been conveyed by one of the people dealing with these. The two house-officers setting up the drip were radiographed with negative results, but a further endeavour to pin-point the source of infection after a lapse of months is likely to be profitless.

The other, less likely, possibilities are as follows:

(1) That a sterile hæmatoma formed at the site of the injection, which was infected from a transient tuberculous bacteræmia from some other source. This can be dismissed as a practical possibility, as we have been unable to find any evidence of tuberculosis elsewhere.

(2) That the injection activated a pre-existing localised focus of tuberculosis, such as a lymph-gland or a bursa. We regard this as equally unlikely, since no such structures are described in this position.

(3) That the infection tracked as a cold abscess from some distant source and was not connected with the penicillin therapy. We have conducted an exhaustive search in an endeavour to prove this happy solution, but clinically and radiologically we have been unable to do so. At this

GOUT IN LEUKÆMIA

REPORT OF A CASE

L. M. SHORVON
M.B. Lond., D.A., D.C.H., D.P.M., D.M.R., D.M.R.T.
SENIOR RADIOTHERAPIST, E.M.S. CENTRE, MOUNT VERNON HOSPITAL, MIDDLESEX

IT has long been a matter of great interest that, though the uric-acid content of the blood is increased in leukæmia, gout hardly ever occurs in this condition.

Forkner (1938), in his exhaustive monograph, could only cite Roberts and Rose Bradford (1907), Schultz (1931), Brunner (1932), and Vining and Thomson (1934) as having reported cases in which the two diseases coexisted.

Roberts and Rose Bradford, in their article on gout, state that "in myeloid leukæmia the quantity of uric acid produced and voided in the urine is greatly increased, and it might have been expected that persons so affected would exhibit a strong proclivity to gout. This, however, does not appear to be the case." They only encountered one patient in whom the two diseases were associated, and that patient had had gout for many years before myelogenous leukæmia arose. They could find no case in which gout supervened as a result of myeloid leukæmia.

Vining and Thomson, in reporting their case of gout and aleukæmic leukæmia in a boy aged 5 years, also state that they could find no case in the literature of gout supervening on a leukæmia.

The present case is thus of special interest in that acute gout developed for the first time in a patient undergoing treatment for leukæmia.

CASE-RECORD

A man, aged 37, was admitted to Mount Vernon Hospital under my care on May 16, 1945. He complained that for the previous ten weeks he had been feeling "sluggish," his abdomen had been getting prominent, and he was dyspnœic on exertion. He had no cough, loss of weight, or pain, and bowels and micturition were normal. There was no family history of gout or leukæmia. The personal history showed that he had had pleurisy in 1931 and 1935. He had been to India but had not contracted any illness there.

On examination he was of rather spare build, with slight pallor of skin and conjunctivæ. Abdomen enlarged; no petechiæ. Throat clean, tonsils moderately enlarged, no gingivitis, teeth in good condition. Clinical examination of lungs showed no abnormality except a slight pleural rub audible at the level of the seventh rib in the left axillary line, probably the result of previous pleurisy. Trachea central. Heart showed no enlargement, no murmurs, and rhythm regular.

The abdomen was distended, practically the whole of it being occupied by an enormous spleen, which formed a firm smooth non-tender swelling which descended from und left costal margin right across the abdomen and down to right iliac fossa, with well-marked notches on the an border. No enlargement of liver, no ascites, no pel glands, no sternal tenderness. Ophthalmoscopic examin was normal.

Examination of the blood next day showed Hb 56%, white cells 354,000 per c.mm. (polymorphs 42%, lympho 3%, myelocytes 46%, and myeloblasts 9%).

The diagnosis of chronic myeloid leukæmia was definitely established, and it was decided to treat the by deep X-ray therapy applied to the spleen. This started on the 18th. The factors used were kV 190, an filter of 0·5 mm. Cu, focus skin distance 40 cm., size of 10 × 15 cm. Each treatment consisted of 100 r incident the spleen.

Three days later, May 21, the patient developed a ty attack of acute gout. He complained of sudden ons severe pain in the right toe. His temperature was 99·5 The metatarsophalangeal joint of the right great toe bluish red, somewhat swollen, and very tender. The sit maximal tenderness was on the medial aspect of the The pain was aggravated by pressure and movement. other joint was affected.

Progress.—I treated the patient with colchicum an decided to continue the rontgen therapy. The affected j during the subsequent few days became more swollen, the pain was kept in check with colchicum. Ten days the onset of acute gout the swelling of the joint to subside and the temperature became normal. Th leukæmia improved, and the spleen became materially smal Irradiation was discontinued on June 1. The tab summarises blood examinations performed between May 1 and July 4.

The patient left the hospital on July 5 feeling very fit

* mg. per 100 c.cm.

DISCUSSION

Gout is commonly regarded as a disordered pur metabolism characterised by (1) recurring attacks o acute arthritis, (2) an excess of uric acid in the blood i.e., hyperuricæmia, and (3) deposition of urates in th cartilages of the joints and in other structures. Of th joints, the commonest to be affected is the metatar phalangeal joint of the great toe, and this was the *involved in the present case.*

The normal limits of the uric-acid content of blood are 0·7–3·7 mg. per 100 c.cm., with an average 2 mg. per 100 c.cm. In gout the uric-acid content of blood may be increased to an amount two or three ti as great as that in normal blood. Hyperuricæmia is n however, confined to gout and occurs in conditions which gout is almost unknown, notably in cases of re insufficiency, pneumonia, and leukæmia. It has be stated that uric acid is the first nitrogenous constitu to be retained in renal insufficiency, and in uræmia th uric-acid content of the blood may be very large. I pneumonia and leukæmia the increased amount o uric acid in the blood is due to the considerable destr tion of the nuclei of the leucocytes. In these diseases th kidneys excrete large quantities of uric acid but cert eliminate the uric acid as rapidly as it is formed.

The way in which the increased amount of uric a in the blood is produced in leukæmia is briefly as follo The nucleoprotein of the nuclei of the leucocytes broken down by enzymes. It is first hydrolysed, prot molecules being split off and nucleic acid liberated. Th latter consists of 4-nucleotides (H_3PO_4 + base + carb hydrate). The carbohydrate present is either a hex or a pentose. The bases are pyrimidines and puri the latter being adenine (6-aminopurine) and guan (2-amino-6-oxypurine). In the tissues, more especially in the liver, adenine and *guanine are* deaminised hypoxanthine (6-oxypurine) and xanthine (2, 6-diox purine). Hypoxanthine is oxidised to xanthine and th latter to uric acid (2, 6, 8-trioxypurine).

In gout the increase of uric acid in the blood is not regarded as due to increased production as in leukæm but as probably due to diminished excretion by kidn with normal production. Gout is not a primary re *ispension.*—A single light-weight and readily adjust- elastic band passing just below the lobes of the ears 2) holds the mask in position. The simple ring- hook fastening permits of rapid removal with one d (useful in cases of vomiting, &c.).

eservoir Bag.—The thin latex bag is very similar to B.L.B. design. Its patency is ensured by the posi- of the inlet tube, which holds its neck open (fig. 3). rainage plug is provided in the bottom of the bag the removal of excessive fluid due to condensation. conical bag made from thin ($^{6}/_{1000}$–$^{8}/_{1000}$ in.) -toxic polyvinyl chloride sheet and sealed by heat in igh-frequency electric field may be used instead of latex bag. The polyvinyl chloride bag is cheaper, es indefinitely, and is less vulnerable ; but the latex is more elastic.

nlet Tube.—This is made by extrusion of polyvinyl oride and has an internal diameter of $^{1}/_{8}$ in. The narrow e and fine tube are an innovation which much reduces ght and bulk.

ADVANTAGES

ince the mask incorporates the reservoir-bag partial- reathing principle, it is economical in gas. In aviation s efficient up to an altitude of 30,000 ft. in warm air- ft, maintaining a satisfactory oxygen saturation of blood with the user at rest and on minimal standard gen flows.

omfort.—The chief advantage in this mask lies in its lightness, the entire assembly weighing only $1^{1}/_{2}$ oz. The great reduction in weight adds enormously to the wearer's comfort, which is further enhanced by the smooth finish of the mask and the low resistance to breathing.

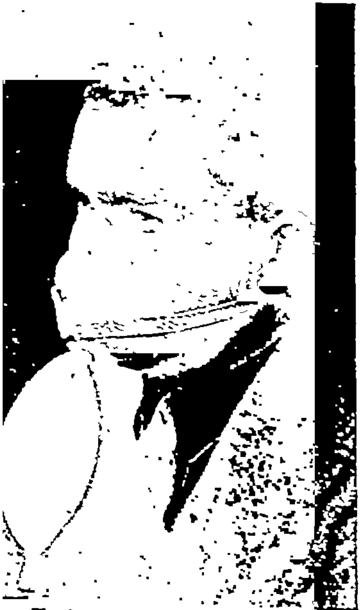

Fig. 2—Mask and bag in position.

Plasticity.—The plasticity of polythene varies imperceptibly with large changes of temperature; in this useful characteristic it is unlike plastics of the polyvinyl chlor- e group, which are renowned for variability of plasticity th fluctuations of temperature.

Sterilisation and Cleanliness.—The extremely low cost the finished article enables it to be thrown away after e, thus overcoming the usual difficulties and incon- nience of sterilisation. This is particularly advan- geous in cases of phthisis and infectious diseases of all pes. If it is desired to retain the mask, it can easily washed and treated with antiseptic solutions. Its smooth finish facilitates removal of sweat, dirt, and condensation.

Acoustics.—Because of the position of the ventilation orifice, conversation is well heard through the mask.

APPLICATION IN MEDICINE

The equipment can be used for routine oxygen therapy in the same manner as the well-established B.L.B. mask and with similar oxygen flows and consumption. For average cases the flow can be adjusted so that the bag remains a little inflated at the end of inspiration.

The mask is less conspicuous if the face-piece is made flesh-coloured or almost transparent. Attractive colours might be a boon in the pædiatric department.

The advantages of so light a mask on the face of a patient in extremis are obvious, the weight being less than a sixth of that of the standard B.L.B. design.

A similar type of transparent face-piece for anæsthetic purposes would provide a mask of less than a twelfth of the weight of those in current use. It would also enable the anæsthetist to observe through the mask itself whether the patient was breathing through nose or mouth, the colour of his lips, the squeezing and pinching of soft tissues, the position of the airway, &c.

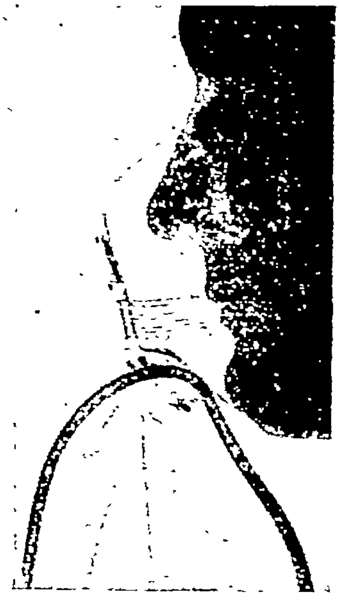

Fig. 3—Radiogram showing how the mask bears directly on bony points above and below, and how the inlet tube keeps the neck of the bag patent.

SUMMARY

A light-weight oxygen mask of new design, with a plastic (polythene) face-piece, though designed for aviation, could readily be applied to anæsthesia and oxygen therapy.

The complete assembly weighs only $1^{1}/_{2}$ oz. The face-piece is so cheap that it can be thrown away after use, is inconspicuous, and interferes little with conversation.

I am indebted to the Director-General, Medical Branch, Royal Air Force, for permission to publish this paper; to the Director of the Institute of Aviation Medicine, Farnborough, where the development was carried out; and to those colleagues who assisted, criticised, and encouraged, particularly Flight-Lieutenant A. J. Barwood and Flying Officer J. D. Wilson.

PICROTOXIN IN BARBITURATE OVERDOSAGE

T. Nauth Misir
M.B. Lond.
ASSISTANT MEDICAL OFFICER, OLDCHURCH COUNTY HOSPITAL, ROMFORD

Picrotoxin is now accepted as the drug of choice in the treatment of barbiturate poisoning. It is a powerful convulsant which acts mainly on the medullary centres, stimulating in particular the respiratory centre.

Duff and Dille (1939) have proved by animal experiments that picrotoxin rapidly disappears from the blood. Very soon after injection the blood-picrotoxin level falls and becomes steady in about 20 min. After 2 hours the quantity in the blood is negligible as picrotoxin is taken up by the tissues. For this reason the drug should be given either intravenously or intramuscularly in small doses and at short intervals—e.g., 15–30 min. Only in this way can an effective concentration be maintained in the blood.

Overdosage of picrotoxin manifests itself by convulsions, which can be countered by the slow intravenous stage it does not seem likely that such a hidden focus would remain obscure.

On the assumption that the infection was introduced at the time of the penicillin therapy, the incubation period, until clinical manifestations appeared, was about four months.

Our chief reason for publishing the case is to draw attention to this serious complication of penicillin therapy. We appreciate the fact that the probable solution lies in some flaw in the aseptic technique used, though it is possible that the infection gained access to the penicillin during its manufacture. Penicillin is now used so extensively that it is not unlikely that similar cases might occur. Knowledge of the possibility of this happening would lead, we hope, to added care in its administration. It should at least lead to a routine examination of post-penicillin abscesses with a view to excluding tuberculosis.

SUMMARY

A tuberculous abscess developed at the site of intramuscular injections of penicillin.

The *infection took about four months to cause* symptoms.

The source of the infection was in all probability either the penicillin or the apparatus for its administration.

Post-penicillin abscesses should be examined for evidence of tuberculosis.

The importance of aseptic technique in the administration of penicillin is emphasised.

Our thanks are due to Sir Claude Frankau, under whose care the patient was admitted, for permission to publish this case.

LIGHT-WEIGHT OXYGEN MASK OF PLASTIC MATERIAL

BASIL S. KENT
M.B. Lond., D.A.
LATE SQUADRON-LEADER R A.F.V.R.
From the R.A F. Institute of Aviation Medicine, Farnborough, Hants

THE mask to be described was primarily designed as a passengers' disposable oxygen mask for altitude flying in the Royal Air Force, but it should have a wide field of utility in anæsthesia and oxygen therapy.

Various materials were tried, such as rubber, paper (including paper impregnated with resins and plastics), cardboards, papier mâché, fabrics (including plastic-coated and doped fabrics), metals (notably aluminium), and plastics. As a result of these investigations polythene was considered to be the most suitable material. Polyvinyl chloride or cellulose acetate can be used but have some disadvantages.

CHARACTERISTICS OF POLYTHENE

Polythene, an odourless vinyl-type resin and a simple polymer of ethylene, was developed in this country by Imperial Chemical Industries Ltd. and is sold under the trade name of 'Alkathene.' It is a thermoplastic material which readily lends itself to both compression and injection moulding. Despite its delicate appearance and the thinness to which it can be moulded, it is very strong, pliable, and resistant to tearing, though extremely light. Owing to the inert nature of polythene, a mask made of it is virtually non-irritant and does not cause dermatitis, as rubber mouldings sometimes do. Polythene will burn, but less vigorously than rubber. It costs about 1s. 2d. per lb. Since a polythene face-piece weighs about $^1/_2$ oz., the material for each will cost about $^1/_4$d. Polythene is 100% reclaimable—i.e., it can readily be remoulded and used again.

THE MASK

The mask consists of a thin polythene face-piece to cover the nose and mouth, incorporating a gauze-covered ventilation orifice and slots for a single elastic strap, reservoir bag, into which oxygen is delivered throu fine inlet tube, is attached (figs. 1 and 2).

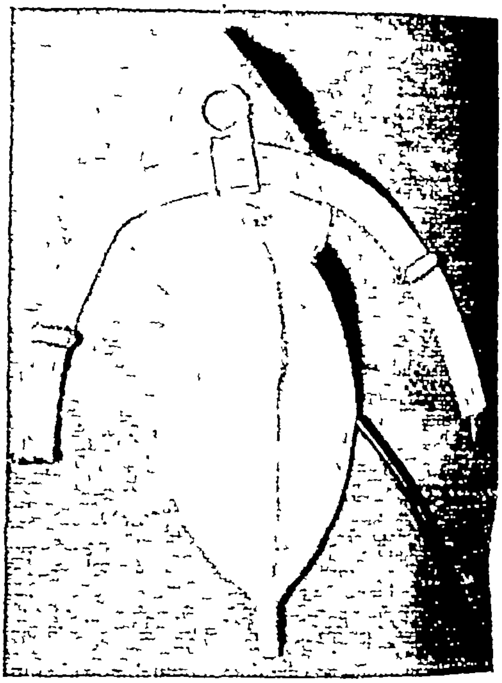

Fig. 1—Polythene mask and latex reservoir bag.

Face-piece.—The oronasal moulding has been to fit on the face and not over the face. The ne for odd appendages has been eliminated, as the operating as *both inlet and outlet valves, the* slot the suspension strap, and the bevelled turret over the reservoir bag is slipped are incorporated in the moulding. The shape gives a reasonably curve tapered bearing surface round the periphery. In a mask to fit the face, the measurement from the of the nose to the tip of the chin (the nasion- is most important; radiography shows (fig. 3) th this axis the bearing points of the face-piece are di over bone—the nasal bone above, and the tip of mandible below—and that the face-piece has shaped to stand well clear of the nasal contour, varies widely from subject to subject. A comfort visual field has been retained, and glasses may be with the mask in position. A suitable dead space— 75 c.cm. on an average face—has been achieved orifice housing, the suspension slots, and the most for point of the bevelled turret are in alignment, so f tating packing and eliminating the projections easily catch in aircraft fittings, bed-clothes, &c. Th type of mask can be made in different sizes to children or adults.

The face-piece is made by injection moulding, liquid polythene being forced into a special mould u high pressure. Advantages of this method are rapidit *output by unskilled labour (about fifty* times as fa rubber moulding), cheapness, uniformity of shape, a very low rejection-rate combined with econom material, since all trimmings and rejects are reclaim

Ventilation Orifice.—A phosphor-bronze gauze (mesh) covering an orifice 11 mm. in diameter act both an inhalation and an exhalation valve. The resist of this arrangement is so low as to be unnoticed even wh no gas is flowing. It will adequately cope with inspiratory and expiratory velocities. The position the orifice does not cause overdilution of the inspi gases. Turbulence created by the gauze mesh advantage at high inspiratory and expiratory flow was much to suggest that the focus he described from primary infection. As Scheel and Heimbeck emphasised in 1928, the problem must be solved repeated examination of individuals with primary tions. In 1938 Malmros and Hedvall had claimed phthisis started in small or moderate-sized cloudy s, which were often multiple and might originate in supraclavicular region and/or in the first intercostal e. In 1944 Frostad had shown that of 135 cases hthisis 48 had developed directly by breakdown from primary focus or its immediate vicinity; in many s he had demonstrated cavitation in the primary ction area. By a series of X-ray examinations, he also shown in 11 cases that the quiescent primary us was reactivated after a long interval, breaking down destructive pulmonary tuberculosis: in others tructive pulmonary tuberculosis developed from an irely new infiltration at another site.

Dr. Ustvedt said that phthisis could develop in the owing ways: (1) direct from the primary lesion or neighbourhood; (2) by reactivation of latent primary i; (3) from metastatic foci of hæmatogenous, lympho- ous, or bronchogenic origin; or (4) through new foci superinfection. It was thus important to detect mary infection, and to observe it carefully for the t few years.

Dr. S. Roodhouse Gloyne (London) asked whether ividual morbidity was related to the typical mortality ves. There was evidence that many primary infec- ns occurred outside childhood. To recall Koch's phe- menon, the most significant part was the necrosis— cardinal sign of the reinfection—and this could be oduced with a large enough dose in the primarily ected guineapig, in which the naturally progressive ease was its own sensitising agent. But had the enomenon any relation to haphazard infection in an? There were two schools of thought. According one, man was infected only once in his lifetime and bsequent tuberculous disease resulted from the main- nance of the original infection. The other held that esh infection was possible, but paid little heed to the e of the all-important original dose.

Precise knowledge of the time-sequence in the "post- imary" phase was lacking. Perifocal satellite lesions ound the primary focus spread to the lymphoid llicles in the walls of the small bronchi. The disease ight then become indolent or quiescent or it might ogress until a small caseous lesion ulcerated into a onchus; this marked the end of the postprimary age and the beginning of the chronic bronchogenic cavating lesion of the adult, of which the outward sign as sputum. On the whole, the evidence for the com- ete healing of the primary complex in childhood was ot conclusive, though abdominal and, still more, cervical imaries tended to heal.

Terplan had shown that age of onset did not neces- rily influence the anatomical appearances of primary fection. He had also collated a series of post-mortem cords in which the first infection was represented by fully calcified complex whilst another complex of a esh infection was also present. He had, moreover, corded cases with primary foci and foci of true exo- nous infection.

The most difficult lesions to assess in the adult were e three types of solitary spherical foci: (1) Assmann's, caseous pneumonic infraclavicular lesion; (2) the rcular focus of Fraenkel confined to no special area of ng; and (3) the pulmonary tuberculoma, probably similar structure to (2). As to the possible causes— etastatic deposits, blocked bronchi, and unusual rimary foci—he had seen lesions which corroborated e last two. but observation had not convinced him at hæmatogenous metastasis was a valid explanation.

The terms "endogenous" and "exogenous" should, e suggested. disappear. Along with the changing inci- ence of the disease and the age of onset, the pathological icture also appeared to be altering. At least five types f lesion could be identified: (1) the childhood primary ocus which heals; (2) the childhood focus which moulders until cavity formation in later life; (3) the hildhood lesion which progresses to bronchopneumonia nd death: (4) the primary focus in a previously tuber- ulin-negative adult; and (5) the healed childhood lesion with adult reinfection of primary type, the latter either also healing or progressing to destructive disease.

Dr. A. Margaret Macpherson (London) described a follow-up of 729 children (over 600 for five or more years), of whom only 7 had developed adult pulmonary tuberculosis. She had been impressed by the number of adolescents with early adult infection, with either a calcified primary lesion or a recent primary focus. Characteristically these patients had no constitutional disturbance, a normal B.S.R. and weight, and a negative family history; glandular enlargement seldom occurred with the lesion, which was in the upper third of the lung and tended to develop into typical pulmonary tuberculosis.

Dr. Walter Pagel (Middlesex) decried the importance of exogenous infection. There were two main types of phthisis, following either (1) immediately after the primary complex, or (2) after an interval. His series suggested that the former accounted for about 25% of cases. On the other hand, he felt that small post-primary foci did not sterilise themselves as easily as the lesions of the primary complex.

Prof. W. H. Tytler (Wales) said that the question would be clarified by large-scale statistical studies; exhaustive pathological investigation restricted the number of cases that could be tackled. The frequency with which primary infection was delayed till young adult life was increasing, but varied in different countries. It appeared that at the Phipps Institute many tuberculin-positives became negative, provided that their original infection had resulted from "no known contact." Did such persons who had lost allergy retain some immunity?

Dr. Ustvedt replied that morbid anatomy was not the most reliable line of approach. The problem of the negative reactor was important, but undoubtedly allergy could be separated from immunity. The form of tuberculosis varied in different countries; in Britain the frequency of calcareous shadows was an impressive feature.

ASSOCIATION OF CLINICAL PATHOLOGISTS

The association's summer meeting at Oxford on July 26 and 27, under the chairmanship of Dr. S. C. Dyke and Dr. A. H. T. Robb-Smith, was opened by Dr. R. Winston Evans (Manchester) with a paper on *Observations on Sickle-cell Anæmia* based on experience in West Africa. Sternal marrow from 20 cases showed that specific changes were not present in the early cells and only occasionally in reticulocytes and normoblasts—i.e., sickling only took place with ease after loss of the nucleus. Sealed, moist preparations typically showed expansion, tenseness, and filamentous extensions 6–8 hours before sickling, and then an explosive onset. Among 600 fit soldiers subjected to routine testing there had been an overall incidence of 19·9%, with the highest—30%—in the Gambians. The clinical findings varied, and might include leg ulceration, which suggested that the sickling was really not the primary lesion but merely superadded to other diseases. Discussion showed general agreement that oxidation-reduction was the important factor. producing sickling in 10–15 minutes, whereas alteration in pH alone had no influence.

Dr. E. Jacobsen (Copenhagen), discussing *Reticulocytes and their Humoral Regulation*, said that if reticulocytes were kept in saline at 40° C there was no drop in their number in 6 hours, whereas when liver was added the reticulocytes ripened very quickly. The liver principle he divided into two parts—a thermolabile fraction absorbed by florodin, and a thermostable fraction not absorbed. The thermolabile portion was a xanthine, of which folic acid was probably a part; stomach tissue also contained a good deal of the thermolabile fraction. Organs of different animals had different amounts of ripening substance, those with few reticulocytes having the highest ripening value while those with many reticulocytes had a low value. He suggested that increased reticulocytosis might therefore not necessarily mean an increased output from the bone-marrow, but might indicate a decrease in the ripening factor.

Dr. S. Wray (Harrogate), in a paper on *Acid Phosphatase* based on 25 cases of prostatic carcinoma, explained the method of estimation and its increase in prostatic carcinoma; it was probable that maintenance doses of administration of a soluble barbiturate. In cases of barbiturate poisoning very large doses of picrotoxin have been administered with success. Kohn et al. (1938) report recovery after 671 mg. of picrotoxin had been administered in four days, and Richards and Menaker (1942) mention recovery after 1944 mg. The largest amount given appears to be 2134 mg. (Rovenstine 1938).

CASE-RECORD

A woman, aged 24, was admitted to hospital at 12.30 A.M. on April 6, 1945, completely unconscious and breathing stertorously. The pupils were of normal size, all the reflexes were absent, and the patient was flaccid. Her mother believed that the patient had taken about 50 pink tablets some $5^1/_2$ hours previously. The patient was last seen going to her room at 7 P.M. and was found at 7.30 P.M. lying unconscious on the floor. Part of a tablet was brought to hospital. It was presumed to be 'Soneryl' and this was later confirmed. Each tablet contained gr. $1^1/_2$ of soneryl. The patient worked as a packer at a nearby drug-manufacturing firm.

A stomach washout was immediately performed, but the fluid returned was clear. Picrotoxin 10 mg. was injected intravenously at once, but with no effect. A large amount of an aqueous solution of picrotoxin was then made up, and about 2 hours after admission intramuscular injections of 5 mg. doses were started. These were continued at 15-minute intervals throughout the days of the 6th, 7th, 8th, and 9th, except for a few short lapses of 2 hours each on the 8th and 9th. Fresh amounts of picrotoxin solution were prepared daily.

At 11.15 P.M. on the 9th the patient became restless and showed signs of returning consciousness. The picrotoxin was therefore discontinued. She relapsed, however, into unconsciousness, and the drug was started again 3 hours later. It was finally discontinued at 5.15 A.M. on the 10th, when she had definitely regained consciousness.

During her unconscious period she was fed nasally with small glucose feeds. The head of the bed was raised. She became febrile and chesty on the 8th. She was therefore put on sulphathiazole in full pneumonia doses, but this had little effect on the temperature, so it was discontinued after 3 days. On her return to consciousness she was found to have a right lower lobar pneumonia. This developed into an empyema. Rib-resection was performed, the empyema cleared up, and the right lung expanded fully. She then developed a left-sided empyema, for which she also had a rib-resection. The patient was discharged from hospital on Sept. 7, 1945, but continued to attend the outpatient department for dressings. She was finally discharged on Feb. 15, 1946. Radiography on that date showed clear lung fields.

She had confessed to taking 100 tablets—i.e., gr. 150—of soneryl on the night of her admission to hospital.

COMMENTS

This patient was unconscious for $4^1/_2$ days, during which time 1745 mg. of picrotoxin was administered by intramuscular injections, except the first dose, which was given intravenously. She appeared to tolerate the drug well, and it did not seem to have any adverse side-effects.

The development of the right-sided pneumonia must have been a consequence of her long period of unconsciousness. The left-sided pneumonia followed the operation for the first rib-resection.

Lumbar puncture with withdrawal of cerebrospinal fluid was not done deliberately, because I wanted to gauge fully the effectiveness of picrotoxin.

POSTSCRIPT

Since the above report was written, I have had to treat another case of gross barbiturate poisoning.

A woman, aged 38, was admitted unconscious to hospital at approximately 2 P.M. on June 17, 1946. The history suggested an overdose of 'Luminal' (phenobarbitone), and she afterwards confessed to having taken 40 luminal tablets, 18 soneryl tablets, and 4 'Nembutal' capsules at about 10 P.M. on the previous night. She had therefore been unconscious for at least 14 hours before admission.

She was deeply comatose and flaccid, and all reflexes were absent, including the pupillary light reflex and the corneal reflex. She was given three ampoules of nikethamide (1·25 g.) intramuscularly and later 10 mg. of picrotoxin intravenously, but did not respond. Regular doses of picrotoxin—5 mg. every fifteen minutes, intramuscularly—were commenced at 4.15 P.M. on June 17 and continued until 5 P.M. on 20th except for short intervals when the patient to be regaining consciousness. On the evening of the she became very restless and was almost fully co All her reflexes were present. Picrotoxin was discontinued. By next day she was fully conscious and able to speak rationally. Nasal feeding was then stopped.

On June 19, while she was still unconscious, she be febrile and "chesty," with bilateral basal crepitations. was put on sulphapyridine in full pneumonia doses by muscular injection. She responded well to this and it stopped on the 25th. Radiography of the chest on the suggested slight consolidation at both bases but on July lung fields were clear. She was then discharged from ho

Throughout her period of unconsciousness she was with the head of the bed raised, and was fed by nasal t

In this case the patient was unconscious for 14 hours before treatment was started, and recei total of 1020 mg. picrotoxin in three days.

My thanks are due to Dr. E. Miles, medical superint for permission to publish these cases, and to Mr. R. E. Fri the hospital pharmacist, for his help in making up the la quantities of picrotoxin solution required.

Medical Societies

TUBERCULOSIS ASSOCIATION

On July 19, the second day of the association's Ox meeting, with Dr. **Norman Tattersall**, the presid in the chair, a discussion on the

Relationship between Primary and Adult Pulmonary Tuberculosis

was opened by Dr. **Hans Ustvedt** (Norway), who s that the divergent views on the subject were due to national variations in the epidemiological picture The dogma of universal childhood infection had killed by the agreement at the 1937 Lisbon confer that primary infection now occurred chiefly du puberty and early adult life. With good conditions observation it was found that about a third of prim infections were accompanied by demonstrable Differences between children and adults were not gr though there was a *malignant* type, primary infe often had a benign course. On the other hand, destru adult tuberculosis had had a characteristic max between the ages 15 and 30, though this was appar being levelled off throughout adult years. Tubercul dissociated from immediate primary infection origin (apart from the probably few cases of superinfect in reactivated latent foci or in "postprimary" stases from foci in lymph-glands or other organs. interval between primary and postprimary disease in most cases under 5 years, and was often only years. Scandinavian figures, using erythema nod as an index of the start of infection, showed that morbidity curve of serious disease had a high peak in first five years, and especially in the first year. Pleur most often appeared within six months, and there a large concentration of disease in the years immedi following the pleurisy. Norwegian statistics also sho that the steep rise in the morbidity and mortality cur nearly synchronised with the age-group at which number of new infections was greatest and the five- period thereafter.

Theoretically, destructive pulmonary tubercul could develop directly from the primary focus or immediate neighbourhood by breakdown, or it co start from a new focus in another part of the lu Outside Norway much emphasis had been placed the latter method; Radeker's "Frühinfiltrat," wh was usually subclavicular, was not compatible the theories of development from tiny apical and his claim that it was due to superinfection not buttressed by adequate tuberculin testing,

Vitamins in diseases of the mouth

Unhealthy oral conditions may result from dietary deficiencies. Appropriate correction of such deficiencies at an early stage may prevent the development of more serious conditions.

VITAMIN A deficiency

This may cause hyperkeratosis of the gums as well as over-growth of epithelia elsewhere. It causes hypoplasia of the enamel organ in experimental animals and there is evidence that vitamin E deficiency has a somewhat similar effect.

VITAMIN D deficiency

This affects the developing enamel, dentine and alveolar bone. Calcium deficiency aggravates its effects.

VITAMIN B_1 deficiency

Small herpetiform vesicles may appear under the tongue or on the palate. They clear up quickly on vitamin B_1 treatment.

RIBOFLAVIN deficiency

This produces cheilosis and a magenta-coloured glossitis, unaccompanied by gingivitis (unless this arises from other causes).

NICOTINIC ACID deficiency

The specific glossitis is fiery red and painful. Gingivitis characteristically accompanies it (contrast riboflavin deficiency) also generalised symptoms — weakness, lassitude, insomnia, headache.

ASCORBIC ACID deficiency

Hyperæmia occurs with swelling of the interdental and marginal regions of the gums which are tender and bleed easily. The gingivitis though not directly due to the deficiency usually responds to ascorbic acid administration.

Further particulars of the various vitamin products available for the above conditions are obtainable on request from:

VITAMINS LIMITED

(Dept. L.X.G.), Upper Mall, London, W.6.

FERTILOL

(Vitamin E and all the other factors of Wheat Germ Oil)

Used in the treatment of habitual abortion, sterility of dietary origin and certain neuro-muscular degenerations.

Fertilol is a highly active natural and stable source of vitamin E and of the other factors of wheat germ oil. Each 5 minim capsule is standardised to contain 3 mg. *a*-tocopherol.

> *Wheat germ oil has, in some trials,[1] shown properties additional to those of pure a-tocopherol.*
>

Further particulars from Vitamins Limited, (Dept. L.F.I.), Upper Mall, London, W.6.

Preventing complications of childbirth

Experience shows that pregnancy and labour present fewer untoward incidents when the expectant mother increases her consumption of milk, fresh fruit, salad, vegetables and vitamin B-containing foods, supplemented by vitamins A and D.

In cases where such a protective regime presents difficulties, a multiple supplement is the best safeguard. A course of Pregnavite raises the intake of important vitamins and minerals to the high level required in pregnancy.

★Pregnavite

in recommended doses supplies:—

★

Vitamin A ..	4,000 i.u.	Calcium ..	160 mg.
Vitamin B_1 ..	0.60 mg.	Iron	68 mg.
Vitamin C ..	20.0 mg.	Iodine	Not less than 10 p.p.m.
Vitamin D ..	300 i.u.	Manganese	
Vitamin E ..	1 mg.	Copper	
Nicotinamide..	25 mg.

œstrogens would be necessary for the rest of the patient's life.

In a discussion on the *Reliability of Clinical Hæmoglobinometry* Dr. R. G. MACFARLANE (Oxford) showed how in a series of investigations a 20% difference between two examiners had occurred. Eight men and eight women had been chosen—four trained and four untrained men and the same in the women. Heparinised blood was tested by sixteen methods on sixteen samples by sixteen observers. The results showed no real agreement between the different methods and the base line of the National Physical Laboratory, in which iron is estimated by King's method. The conclusions on the significant errors were that differences of 4% were significant with any one observer and 5% with any two observers. Dr. I. D. P. WOOTTON (London) showed that colorimetric methods agreed more closely with iron estimations than did gas analysis; it was suggested that grey wedges should be used, calibrated directly in grammes of hæmoglobin. Dr. MACFARLANE suggested that the original N.P.L. standard of 13·8 g. per cent. was too low and 14·7 g. per cent. should be accepted as the standard hæmoglobin.

Dr. JANET VAUGHAN (Oxford) spoke on the *Inci* *of Homologous Serum Jaundice after Transfusion* observations at the North-west London Transf Depot. Of 2040 patients followed up five months transfusion, only 1084 could be included in the se of these, 77 (7·3%) had developed jaundice. In a trol group no cases of jaundice occurred. The incuba period after transfusion was 50–150 days, with majority between 60 and 100 days. All cases were in contrast to other centres, where several deaths been reported. Fewer cases followed whole-blood tr fusion than plasma or serum, probably because thi pooled. Serum for prophylactic purposes should be pooled, and for transfusion only the smallest should be used; *and all blood products should* an identification number, so that records could easily checked.

Reviews of Books

Control of Pain in Childbirth

(2nd ed.) CLIFFORD B. LULL, M.D., F.A.C.S., clinical professor of obstetrics, Jefferson Medical College; ROBERT A. HINGSON, M.D., surgeon U.S. Public Health Service, director, postgraduate medical course, Philadelphia lying-in unit, Pennsylvania. London: W. Heinemann. Pp. 348. 42*s*.

THIS book could be read with advantage by every obstetrician in this country, and by every anæsthetist who attends obstetric cases. All practitioners who do midwifery would find it helpful. We are a long way behind the United States in obstetric analgesia and anæsthesia, and Professor Lull and Dr. Hingson stimulate us to improve our own well-tried techniques, if not to expand the scope of our obstetric analgesia. They have written a good and comprehensive section on anatomy and physiology, and they review and assess all known methods of anæsthesia and analgesia, using clear and attractive diagrams to illustrate the action of each drug on the various systems. They have a proper bias towards local and caudal anæsthesia, and put in a strong plea for the use of continuous spinal anæsthesia. These methods have much to recommend them; but British obstetricians have never liked them and so get disappointing results. Let them read this book carefully and try again. There are good chapters on analgesia in domiciliary midwifery, neonatal resuscitation, and anæsthesia in cæsarean section. We have no comparable volume by British authors.

A Handbook of Social Psychology

KIMBALL YOUNG, professor of sociology, Queen's College, New York. London: Kegan Paul, Trench, Trubner. Pp. 578. 21*s*.

NOBODY questions the importance of social psychology, but many doubt whether it yet has independent scientific status. Prof. Kimball Young's exposition partly answers such doubts, but contains too much discussion and too little experiment to allay them wholly. In a field which touches daily life so closely, a textbook must do more than state, examine, illustrate, and organise matter which is within everyone's knowledge; and the well-informed reader will require that it should enable him to correct his erroneous beliefs, and to enlarge the stock of facts and generalisations through which he can predict the outcome of known circumstances. This the book does insufficiently, in spite of the author's wide range, critical erudition, and lucid grasp. There are three main divisions: the first deals with basic relations of personality to society and culture, the second with human conflict, and the third with mass behaviour. In the first there are chapters on animal behaviour, drives and emotions, factors in learning, the mechanism of personality, stereotypes, myths and ideologies, and dominance and leadership. Prejudice, revolution, war, and morale are expounded in the section on human conflict; problems of crowd behaviour, fashion, public opinion, propaganda, and power make up the final division of the book.

Cardiovascular Disease in General Practice

(2nd ed.) TERENCE EAST, D.M. Oxfd, F.R.C.P., physic in-charge of cardiological department, King's Col Hospital, London. London: H. K. Lewis. Pp. 198. 12*s*.

UNLIKE most of his fellow authors, Dr. East h succeeded in bringing out a new edition of his bo which is actually shorter than the original. This typical of his approach to his subject: he restricts hi self to aspects of cardiology important to the m in practice. No unnecessary words are used; ind at times the style is almost telegraphic. The teachi is essentially sound, though many will deprecate t choice of cæsarean section for delivery of the mot with heart-failure. Pruning of the section on anæ and heart disease would have left room for fuller exp tion of the important subject of heart disease in old

Howell's Textbook of Physiology

(15th ed.) Editor: JOHN F. FULTON, M.D., Sterling fessor of physiology, Yale University. London: W. Saunders. Pp. 1304. 40*s*.

THE editor of this edition of the well-known originated by Howell has delegated many sectio different writers. In the main, it is a sound exposi of the subject with a strong physical bias; thus, th are good chapters on hæmodynamics, and on mus nerve physiology and electrical changes in the The nervous system is also unusually well treated. the section on the circulation is full of fundame information. Many students will feel the book is w having for these sections, which occupy more than thirds of it. The remainder is also good, but respira metabolism, nutrition, excretion, and reproduction not dealt with in the same detail, and there is no sep section for the endocrine organs. When as many pages are allotted to the electrocardiogram and interpretations, this seems parsimonious. In spite of criticisms, which are chiefly of imbalance—a d almost inseparable from multiple authorship—the reaches the status of a standard work.

Experiments with Mammalian Sarcoma Extract

in regard to cell-free transmission and induced immunity. CARL KREBS, OSKAR THORDAR JOHANNES HARBO, from the Aarhus Kommune Hosp Röntgen and Lysklinik. Translated by Robert Fr Pp. 96.

THESE further studies of the Krebs, Rask-Niel Wagner sarcoma were undertaken to find out if tumour is produced by a virus and is capable of cell transmission, and also in an attempt to increase resistance of mice against inoculation with tumour Neither object has so far been attained, but the valu this work lies in the detailed description of the procedu adopted. Cell-free transmission of mammalian sarco has on occasion been successful, but never repeatable will. It seems therefore that the crucial factor has some neglected trifle or totally unsuspected conditi These authors record one experiment only in wh cell-free transmission may have occurred. They conclu that they have no evidence to support the hypothe that mouse leukosis is caused by a virus.

THE LANCET

LONDON: SATURDAY, SEPT. 14, 1946

B.C.G.: the Next Phase

y his social experience through the centuries, opean man has acquired a fair resistance to rculosis; but until the introduction of B.C.G. ine the bacteriologist had failed to add one cubit ts stature. From the "brownish-clear fluid which lurable in and for itself," which Koch called rculin, to the bacillus which Calmette and rin isolated from "lait du Nocard," the tale of e vaccines is a long one, and it is written in the books for those to read who wish. But most of se vaccines belong to the past; they are dead, h metaphorically and literally, excepting only .G.

ntroduced by Calmette shortly after the first rld war as a means of protecting children born tuberculous households in Paris, B.C.G. vaccine passed through several critical phases. Oral ministration, which was first employed, was too phazard and came to a dramatic end under the probrium of the Lübeck affair, for which it was in fact responsible. Subcutaneous and intra- taneous inoculations followed, but caused many abscesses at the site of inoculation. Quite recently .G. has successfully negotiated the trial of two transcutaneous methods—a scarification and a ltiple-puncture technique. As to its real efficacy, ny international discussions have raised the tem- rature amongst the critics, and no useful purpose uld be served at this late stage by going over all e arguments which concerned the experts in the alth Organisation of the League of Nations. Four ts, however, stand out from the mass of official ports and protocols of experiments: (1) the Cal- ette-Guérin bacillus is harmless to man; (2) culation with it increases resistance to tubercu- sis; (3) the degree and duration of this immunity ve not yet been precisely determined; but (4), like e immunity conferred by other bacterial vaccines, is not permanent.

An impressive array of information collected from rious parts of the world has recently been set forth the European regional office of Unrra[1] and in a morandum, prepared by Prof. W. H. Tytler,[2] ich has been presented to health departments ntly by various tuberculosis organisations.[3] These dies have made it clear that informed opinion is w in favour of a clinical trial of B.C.G. in this untry, and they also advocate a single source of pply under official control. Because of the earlier cteriological reports on the unstable virulence of e bacillus, and because of the Lübeck incident, ess has rightly been laid on the care with which e vaccine should be prepared by the laboratories. When a vaccine is made of living micro-organisms, almost as much concern, however, should be felt about its care when it is no longer under the watchful eye of the bacteriologist who has prepared it.

The subcutaneous and transcutaneous methods of giving B.C.G. have been pioneered chiefly in Scandinavia. The Norwegians began with tuberculin-negative nurses and then went on to immunise groups of the general population. Later B.C.G. was introduced for the Norwegian forces in Britain, and between 3500 and 4000 were inoculated. This group deserves special mention because it is the only large body of persons immunised while living in this country; but so far as we know the results have not yet been published. It has been claimed that the vaccine "gives a standardised innocuous primary infection," but the Unrra bulletin emphasises what is regarded as a contra-indication to its use—namely, a latent allergy in the individual. It points out that

> "In Scandinavia nurses undergoing B.C.G. vaccination are completely segregated; there is an ante-vaccinal period of isolation, during which all the requisite preliminary investigations are made, viz., tuberculin testing, radiography, ascertainment of home conditions to eliminate the possibility of recent infection. Thereafter the vaccination is carried out and, one month later, the individual is tuberculin tested. Should the reaction prove negative, the individual is segregated for another month and again tuberculin tested."

If these difficulties have been overcome in Norway, there is no reason why they should not be tackled here, but with the present shortage of staff they will not be easily surmounted. The memorandum presented to the health departments advocates a trial—purely voluntary—with selected groups of people who are exposed to unusual risks of tuberculous infection. Those who work in hospital—medical students, nurses, and domestics—come to mind at once; and these groups certainly lend themselves to medical supervision, though not all their members are employed very long in one place. In the industries with a high incidence of tuberculosis it might be less easy to arrange appropriate trials; while children in tuberculous households in this country do not in general run such serious risks as they did in Paris when the vaccine was introduced. The primary object of an inquiry should be to determine whether B.C.G. vaccine will give in Britain the satisfactory results claimed for it in Scandinavia, in Canada, and in some other parts of the world. It should be borne in mind that tests on a small scale in New York, where the conditions more closely resemble those of the large British cities, have not been strikingly favourable: moreover, the clinical picture of tuberculosis varies in different countries, racial resistance differs, and neither social circumstances nor anti-tuberculosis measures are the same. Granted therefore that the vaccine is efficacious, it will not necessarily produce dramatic results in this country where infection is already under fair control, and where spontaneous arrest of the disease is very common: it is more likely to do conspicuous good in the devastated and hungry parts of Europe where ordinary precautions have broken down and cannot be restored for a long time; or in the tropics. There are some, indeed, who consider it mere wishful thinking to suppose that prophylactic vaccination will hasten

Bulletin of Communicable Diseases and Medical Notes, 1946, 4, 705.

Memorandum on B.C.G. prepared for Tuberculosis Association, Joint Tuberculosis Council, and National Association for the Prevention of Tuberculosis, 1946; see *Lancet*, July 27, p. 138.

See *Lancet*, July 27, p. 125.

On 1 cc.

The two test cases are typical of many, and fully demonstrate the efficiency of 'Examen.'

Every batch of 'Examen' fulfils in test the criterion of optimum response for one single injection of 1 cc. over 14 days.

This chart shows the required response to treatment for an initial red-cell level of 1.25 million. According to this criterion the final red-cell level must be at least 2.6 million (the crosses indicate the initial and final red-cell levels). The responses obtained in two test cases using 1 cc. of 'Examen' are shown by the continuous lines.

Thus 1 cc. every 14 days is the standard dose in treatment, and 1 cc. every 4 weeks the dose in maintenance.

TELEPHONE: TEMPLE BAR 6785 *TELEGRAMS: MENFORMON, RAND, LONDON* mediate case-mortality of 38%, and 19 one-stage erations with a mortality of 31%, 22 of the opera- ns being for carcinoma and all deaths occurring this group. Cattell,[9] who favours a two-stage chnique for jaundiced patients, has reported 13 o-stage and 5 one-stage operations with 3 immediate aths—an overall mortality of 17%. It is too early assess the remote results, but, as might be expected, tients with growths of the ampulla seem to do tter than those with growths of the pancreatic head. t least these figures falsify the physician's ancient be that the only effect of surgery in pancreatic rcinoma is to let the patient die a better colour.

It would be idle to pretend that American experience these operations is not greater than ours, but only a erverse and foolish modesty would ignore the work of ritish surgeons. Illingworth,[10] Gordon-Taylor,[11] aingot,[12] and Watson[13] have between them recorded cases with 2 deaths, all the successes being with the o-stage operation. This year d'Offay,[14] in a itherto unpublished address to the Royal Society Medicine, described what appears to be the first ccessful one-stage radical operation in this country, s well as 2 other cases, one of whom died. d'Offay mphasises the accuracy of Courvoisier's law in he differential diagnosis of carcinoma and stone, rovided that the law is applied after actual inspection f the gall-bladder through a peritoneoscope rather han by abdominal palpation. Pannett[15] has lso reported 2 successful one-stage operations. he history of the radical operation for pancreatic arcinoma shows that bold thinking has once more onfounded those who contend that surgical technique as reached its zenith.

Efficacy of the Penicillins

It has been known for some time[16] that there are everal chemically different penicillins whose strucures have a common nucleus, but differ in the nature f a side-chain R. So far five different penicillins have een isolated in the crystalline state from culture nedia of moulds. Four of these, which have been tudied in greater detail than the fifth, are now called enicillins F, G, X, and K in the United States, vhereas in Britain they are known as penicillins I, I, III, and IV, according to the historical sequence f their discovery; it is hoped that this confusing omenclature will soon be replaced by a more conruous chemical terminology. The side-chains R of he different penicillins have the following chemical tructures:

For penicillin I (F) C_5H_9 (2-pentenyl)
" " II (G) $C_6H_5CH_2$ (benzyl)
" " III (X) $OH . C_6H_4 . CH_2$ (*p*-hydroxybenzyl)
" " IV (K) C_8H_{17} (*n*-heptyl)

The four different penicillins affect the same range f bacteria, but differ quantitatively in their antiacterial power in vitro. Thus, if we assign a value of 00 to the antibacterial activity in vitro of penicillin I (G), the relative values for penicillins I (F), II (G), II (X), and IV (K) are 90, 100, 55, and 140 against the strain of *Staphylococcus aureus* used for routine assays of penicillin (in international units per mg. the figures are 1550, 1667, 900, and 2300); against a strain of hæmolytic streptococcus the values are 82, 100, 140, and 120, and against a cultured strain of *Spirochæta pallida* Reiter 53, 100, 50, and 75.[17] The chemotherapeutic efficacy of the penicillins, however, like that of all other chemotherapeutic agents, depends not only on their activity in vitro but on a series of other factors, such as absorption, excretion, destruction in the body, &c. It is therefore not possible to predict their effectiveness in vivo solely on the basis of the figures for their antibacterial activity in vitro. Recent evidence shows that penicillin IV (K), notwithstanding its high antibacterial action in vitro, is much less efficacious in vivo than penicillin II (G). Thus, in the treatment of *Streptococcus pyogenes* infections in mice, penicillin IV (K) was only 1/11th as effective as penicillin II (G) and only 1/30th as effective as penicillin III (X), and in the treatment of pneumococcus type I infections in mice penicillin IV (K) was only about 1/6th as effective as penicillin II (G) and 1/8th as effective as penicillin III (X).[17] Similar results were obtained in the treatment of experimental syphilis in rabbits. Here various independent investigators[18] found penicillin IV (K) to be only about 1/10th as effective as penicillin II (G). The explanation seems to be that penicillin IV (K) is subject to greater destruction in the body than the other penicillins. This conclusion must be drawn from the fact that after intravenous or intramuscular injection the blood-levels with penicillin IV (K) drop more rapidly than with the other penicillins, while the proportion of the injected penicillin that is recoverable from the urine is much lower with IV (K) than with the other penicillins,[17, 19] the figures being about 30% and 80%.

The finding that penicillin IV (K) is less efficacious chemotherapeutically than the other penicillins is of considerable practical importance since commercial penicillin is a mixture of different penicillins with an undefined proportion of penicillin IV (K). The amounts of the different penicillins in the commercial products depend on the strain of mould used in production and on the composition of the culture medium. Strains used by manufacturers up to 1944 yielded predominantly penicillin II (G), but since 1944 a change has taken place in the commercial penicillin preparations, leading to a fall in their content of II (G) and a rise in IV (K). Strain Q176, which is now used by most penicillin manufacturers because it gives the highest penicillin yield, is known to produce under certain conditions a considerable proportion of IV (K). A statistical comparison has shown that the results of treatment in early syphilis with penicillin preparations manufactured before 1944 were decidedly better than those obtained with penicillin manufactured in 1944–46. There may be other causes for this than simply a change in the proportion of penicillin IV (K). Since 1944 the purity of the commercial penicillin preparations has increased considerably. Dunham and Rake[20] have produced evidence to show that

the slow disappearance of tuberculosis from our midst, and even fear that it may deflect us from more fundamental efforts at eradication. As Prof. Arnold Rich *has pointed out*, however, a disease which still kills twice as many individuals as any other during the productive period of life cannot be regarded as nearly defeated. There is as yet no easy way to victory over so inveterate an enemy, but it is not too much to hope that immunisation, if wisely handled, will prove a useful weapon.

The clinical trial of B.C.G. which we hope soon to see in this country should be placed in the hands of *a body such as the Medical Research Council* which has the experience, equipment, and personnel for work on a sufficient scale. Only the most carefully compiled figures in significant quantity will satisfy the statisticians. The question also arises whether it should be confined to B.C.G. The vole bacillus discovered by A. Q. Wells shortly before the war[4] *is running the Calmette-Guérin organism very close*, and Birkhaug's latest experiments suggest that in animals its immunising properties are as high.[5]

Excision of the Head of the Pancreas

Hopes of a radical treatment for carcinoma of the pancreas were first raised in 1899 when Halsted excised a segment of the duodenum and part of the pancreas for an ampullary growth; but progress was sporadic until, in 1935, Whipple, Parsons, and Mullins[6] initiated a systematic study. Since then reports of excision of the duodenum and pancreatic head for carcinoma have become almost commonplace in America.

Apart from the rare islet-cell tumour, malignant *growths of the head of the pancreas may be classified* according to their site in two main varieties: carcinoma of the ampulla of Vater or its immediate tributaries grows slowly and gives rise to early jaundice, whereas carcinoma of the head of the pancreas proper is more common, more malignant, and gives rise to jaundice somewhat later. A radical resection of either type necessitates removal not only of the pancreatic head but also of the duodenum, because the lymphatic and blood supplies of the two organs are inseparable. So bold an extirpation (involving as it does the division and repair of the intestinal, biliary, and pancreatic tracts) would scarcely be possible without the recent advances in chemotherapy, the discovery of vitamin K, and the excellence of resuscitative and anæsthetic techniques. The problems of the actual excision are anatomical and are largely concerned with avoiding damage to blood-vessels essential to life. The repair *which follows has its special difficulties. The thorniest* is the treatment of the pancreatic stump; this continues to secrete the most powerful proteolytic enzyme in the body, and mere closure of the cut end has led, through sloughing and digestion of damaged tissues and sutures, to external fistulæ and—still worse—to internal leaking. What remains of the pancreas must therefore be anastomosed to the jejunum, into which it can secrete. The new anastomoses of the biliary and pancreatic tract the intestine have no sphincters, and their ostia therefore be kept away from the main stream digesting food; unless this is contrived, by admi bile and pancreatic juice to the jejunum pro to the gastric opening, ascending cholangitis pancreatitis will result from reflux of food up respective channels and the proximal jejunum be denied the protection from the gastric provided by an alkaline flow from above. Op differs as to whether radical [illegible] should be done in one or two stages. The advo of the *one-stage operation argue that the d* risk of two operations is avoided, that [illegible] adhesions at the second and more difficult are sidestepped, and that the patients, though de jaundiced, can be carried safely through by suffic preparation, particularly with vitamin K. The t stage protagonists hold that these patients are *ill to stand a major procedure without preliminar* biliary decompression; they do not find [illegible] a problem at the second stage if the gall-bladd is anastomosed to the jejunum.

Whipple,[7] doyen of pancreatic surgeons a an advocate of the one-stage operation, has late distilled his wisdom in a formula for the operati *For an ampullary growth the abdomen* is through a right rectus incision from the costal mar to the umbilicus. After a general survey, the pe toneum is incised to the right of the duoden which is elevated to determine the mobility of pancreatic head, and the configuration of the unci process is studied. If the growth appears oper the common bile-duct is divided behind the duoden The stomach is transected proximal to the pylor and the origin of the gastroduodenal artery fro the hepatic artery revealed, ligated, and cut. duodenum is divided proximal to the duodenoje flexure (this stage must be modified if the unci process encircles the superior mesenteric vess and the *inferior pancreaticoduodenal* artery is secur The pancreas is cut across at the junction of head and the body, and the splenic vessels, p vein, and superior mesenteric vessels are dissec off, drawing the pancreatic head to the right. pylorus, duodenum, *lower end of common* bile-d and head of pancreas are now removed en A loop of jejunum is brought up and anastom to the stomach, pancreatic stump, and cut end of bile-duct, from below upwards, so that gastric opening is the most distal in the jejun It seems easier than might be supposed to insert small rubber tube into the pancreatic duct which dilated from obstruction, and to thrust the through a small hole into the lumen of the jejun the cut edge of pancreas is then sutured to the je wall. A drain is inserted and the abdomen clo Whipple attaches great importance to the use silk throughout the operation, because catgut readily digested by any escaping trypsin; and thinks that the gall-bladder should never be to anastomose the biliary tract to the intestin an unavoidable expedient in the two-stage operati

What are the results? Whipple in 1945[8] repor *that he had done 8 two-stage operations* with iile some obstetricians have hailed Read's work as ›neering service to obstetrics, others have decried a new flight of psychiatric fancy. His method has employed in the U.S.A. by Blackwell Sawyer,[2] personally delivered 168 women in a small general ital without the assistance of a resident. His material sted of 62 primiparæ and 106 multiparæ. He had tal death (a premature infant dying twelve hours delivery) and he used forceps 9 times—for occipito- :rior position and deep transverse arrest 4 times for a big head (low forceps) 5 times. He had 1 set wins, and 1 breech and 1 face presentation. In r words, his obstetrical material was fairly repre- ıtive. The women with malpresentations suffered most pain, but of the 106 multiparæ, 90 said that were helped greatly by the method, that they had no during the first stage, and that they concluded the nd stage in two to five expulsive efforts. They were ›ffered ether as an anæsthetic but only 4 accepted There was no hysteria or uncontrollable crying or ıming. They were prepared to go through their ur again, conducted in the same manner: some of women were astonished at the smoothness of their ery. Of the 62 primiparæ, apart from malpresenta- s and forceps for big heads there were 53 cases, of m 5 were frightened, groaning, and complaining ıen all through their delivery and were written off omplete failures. Among the remaining 48 little pain experienced. In 10 of these pethidine was used in s of 50–100 mg., one or at most two injections being n; this "took the edge off the pain" and enabled patients to coöperate. In all primiparæ the perineum injected with procaine and a small episiotomy ormed. Patients with whom the technique was :essful were calm and cheerful.

ıwyer's conclusion is that the method when carefully lied is valuable in relieving the pain of normal dbirth in 90% of cases. The extent of relief varies, it is a positive phenomenon, complete in some and ial in others with whom the minimal use of analgesic gs as an adjuvant will have an added effect. The great wback to the method is that it is very time-consuming, there cannot be many obstetricians in this under- tored country who will have time to apply it properly. t is at least abundantly clear that fear should be ished from the expectant mother, and that if she has confidence in her attendants and the arrangements le for her confinement (and this confidence is the ural corollary of decent and efficient antenatal super- on) then she will have an easier, safer, and speedier our.

THE SICK FAMILY

OCIALLY troublesome families, such as a number of lical officers of health have been investigating in country,[3] were recognised in Holland to be a social blem during the period following the first world war. 1926 a compound or colony was created by the city ncil of Amsterdam on a peninsula between two canals the edge of the city. It consisted of 52 bungalows quately equipped and associated with a kinder- ten, clubroom, and other amenities. Social assistance supervision were arranged, and much effort was put › the scheme. But in the course of years it became lent that it had utterly failed to restore these families ı satisfactory independent way of life: "the village ame a collection of social curiosities and freaks; r the evacuation of the compound these families lived, live, in almost indescribable squalor in the poorer rters of the town." Dr. Arie Querido,[4] who has reported on the matter, draws the picture so familiar in every description of such families—dirt, disorder, fecklessness, neglect, and misery. "Whatever is the prevailing social problem, these families express it in its most acute form. In times of prosperity they are the parasites and petty criminals; when it is difficult to obtain work, they are the first and longest out of a job; when there is a shortage of houses, they are roofless; if there is a shortage of food, they are the first to go hungry."

Dr. Querido, in his capacity as director of the municipal department of mental hygiene in Amsterdam, was asked to look into this question because of the presumed importance of mental abnormality as a cause of the social failure. He was able to classify the families into three groups. In the first the social problem disappeared if certain adverse conditions of health and work could be remedied; the second group of families could never keep its head above water unless it had external help; but the third group was certain to fail no matter what social assistance was provided in the hope of remedying or averting its deterioration. Querido therefore came to regard the severe "social problem" family as a diseased biological unit, of which social deterioration was the chief symptom; he compares the measures that one takes to treat an individual patient who has mental disorder with those which are necessary for the disordered family, and finds them very similar. He is opposed to any such drastic solution as disrupting the family by withdrawal of the children: he compares it to killing a patient and then saying that the problem of his disease is solved. When he calls the social problem family a unit, he evidently means what he says.

To treat the family, two conditions, he insists, must be fulfilled—there must be means of treatment, and power to make these means effective. A committee which has considered the question has put before the Dutch government proposals to this end. A person who is apparently unable, by reason of mental disease or other mental failings, to fulfil his material and moral obligations towards himself and those who are dependent on him, can be placed under legal supervision by order of a judge. When one or both parents are thus dealt with, the supervisor (who is an expert in psychiatric or social work) establishes contact with the family, who must follow his instructions. He will be the guardian of their children, the parents being reduced to the legal status of minors. If attempts to improve the situation fail then the family can be placed, on the supervisor's recommendation, in an institution or camp for a period of a year (which can be prolonged by judicial decision). So far as the means of treatment are concerned, in the first instance the whole family would be placed in an observation camp where thorough psychiatric, medical, and social investigation would be carried out; thereafter the family would be placed in one of the "education camps," providing for about 15 families. While living in this camp the children would go to the ordinary school in the neighbourhood, and the members of the family would work in the ordinary farms and industries of the locality. Social assistance would be at hand for building up the household again. After a successful stay in the camp the family would return to its original locality, but would remain under supervision until the court brings it to an end.

These proposals are drastic and could only be warranted if the problem family presented as serious a menace to society as criminals or dangerous lunatics. Querido maintains that it does: "the course proposed involves a serious infringement of personal liberty and offers possibilities of abuse. On the other hand, the problem family offers serious dangers, is an infectional focus to society and presents an intolerable state of human indignity, so that strong measures are justified."

impure penicillin preparations are more efficacious than crystalline preparations in the prophylaxis of experimental syphilis. It is conceivable—though by no means proved—that during the far-reaching purification of penicillin now carried out an impurity is removed which exerts a synergistic effect on the treponemicidal action of penicillin. In any case it is desirable to keep down the proportion of penicillin IV (K) in commercial preparations to a minimum. Fortunately it appears to be possible to influence the course of penicillin fermentation induced by the strain Q176 in favour of the production of penicillin II (G) by the addition of specific precursors. In future, producers will have to adopt more comprehensive methods of assay. The usual biological method of assaying penicillin preparations, based on their in-vitro activity against *Staph. aureus*, is, in conjunction with toxicity tests, the only criterion now commonly used for their clinical value. This will have to be supplemented by an analytical method which will reveal their quantitative content of the different penicillins.

Annotations

TWELVE-AND-SIX A HEAD

THE controversy between the Ministry of Health and the Insurance Acts Committee over the current N.H.I. capitation fee, on which we commented in our issue of August 3 (p. 166), has been carried some important steps farther. Despite repeated representations by the committee, the Minister has persisted in his view that the adjustment of the current capitation fee and the assessment of the proper mode and amount of remuneration in the new National Health Service are questions which interlock so closely that they cannot be considered separately. The committee, neither accepting this view nor being empowered to take any part in negotiations for the future service, found itself unable to meet the Minister for the discussions for which he asked, and, in default of negotiation, the Minister has now made his proposed award of an increase of 2*s.* in the capitation fee, to 12*s.* 6*d.*, with retrospective effect from Jan. 1, 1946. This he announced in the public press on August 24.

The Insurance Acts Committee met on Sept. 5 to reconsider its position, and it has decided that it can regard this award only as an interim payment and in no way as a final settlement of the long-standing claim of the panel doctor for higher remuneration. It reaffirms its view that the fee of 12*s.* 6*d.* is gravely inadequate, and regrets that the Minister is unwilling to implement now the report of the Spens Committee, whose findings it had been promised would be applicable to National Health Insurance "irrespective of the institution of any National Health Service." It believes further action should be taken, but before doing anything more it has decided to consult the panel committees, and through them the individual panel doctors. It has accordingly submitted the following recommendation for immediate consideration by the panel committees and their constituents, and for subsequent discussion at the Panel Conference due to be held late in October.

> That, in view of the Minister's failure properly to apply the report of the Spens Committee to the current capitation fee—despite explicit Government promises that this would be done—and in view of the grave inadequacy of 12*s.* 6*d.* as remuneration for assuming medical responsibility for an insured person for a year, it be recommended to all insurance practitioners in England and Wales, Scotland, and Northern Ireland to place their resignations from the National Health Insurance Service in the hands of the Insurance Acts Committee and to authorise that committee at its discretion to put in such resignations to insurance committees unless the Minister is willing fully to apply the Spens Report to the current capitation fee with effect at least from Jan. 1, 1946, or, failing agreement, to refer to the Spens Committee or a representative section of that committee or other agreed independent body the interpretation of the Spens Committee Report in relation to the current capitation fee, both parties agreeing in advance to accept the findings of such body.

There is much justice in the contention of the Insurance Acts Committee that the assessment of a just capitation fee for the present service could and should be separately undertaken now. The offer to submit to the judgment of "the Spens Committee or a representative section of the committee or other agreed independent body" is an offer free from intransigeance which makes an agreed settlement still attainable. But even if the Minister will not favourably consider any of these proposals, the frustration of this controversy must not be allowed to delay or obscure decisions which are even more important. Next month the National Health Bill may become law. As soon as it does, the Minister will be empowered to draft regulations of the gravest importance to the future of medicine. The British Medical Association has promised the doctors the opportunity of deciding by plebiscite whether the profession, through its negotiators, shall participate in the drafting of these regulations. The time remaining for the effective taking of this plebiscite grows short and must not be wasted.

PSYCHOGENIC PAIN IN LABOUR

IN the early nineteen-thirties Grantly Dick Read[1] postulated that the pains of labour are caused by fear and that the proper relaxation of the cervix is under the control of the autonomic system, which is connected with the thalamus—the seat of all primitive emotions and notably of fear. Corticothalamic impulses may inhibit the cervix via the sympathetic nerves and set up a state of primary uterine inertia. The uterus may be regarded as a hollow viscus with a detrusor and a sphincter muscle, and it may reasonably be supposed that the action of these two muscles, though primarily antagonistic, is in labour synergistic. The normal polarity between the sphincter and detrusor muscles may be disturbed by impulses from higher centres, and every obstetrician knows that a nervous woman having her first baby, surrounded by solicitous relatives, is a candidate for primary uterine inertia. Read therefore emphasises the importance of reassuring the expectant mother and of engendering such a confidence in her obstetrician, midwife, and institution that she faces labour with a mind calm and relaxed and a body in which the sympathetic nervous system has not got the upper hand of the parasympathetic. Having been instructed in the nature and function of labour she knows what sensations to expect, and does not panic when, for instance, the head distends the perineum. Many women so fortified and instructed can complete their labour without an anæsthetic or with only a minimal amount during the conclusion of the second stage. For such a technique of psychological anæsthesia to be effective the woman must be schooled from her first antenatal visit, and this, of course, demands time and patience on the part of her obstetrician. Read advises that she should be taught how to relax, and instructed to practise relaxation every day. The woman is also shown, by anatomical diagrams, exactly what happens in labour; discussion about the baby is encouraged and the woman's mind is focused on the child and away from herself. It is impressed on her that labour is a great event and a memorable occasion culminating in the lusty cry of a healthy child which it is her great feminine privilege to have borne.

ıe plankton, of which there are three groups— ucers, consumers, and reducers. The producers prise largely the chlorophyll-bearing diatoms and , which by solar energy build up organic matter ı inorganic nutrients in the water. The consumers ooplankton feed on the living or dead matter of this toplankton or its metabolic products, and are in turn sumed by such fish as herring, pilchards, sprats, kerel, and, curiously enough, one of the world's est mammals—the rorqual whale. Much of the ng or dead plankton falls to the sea floor, where it is en by the bottom fauna, including worms and shell- , which in their turn form the food of the bottom- ng fish. The amount of plankton is very large, being ecially rich in some Polar areas, but varies from one ion to another; it has been estimated that in the glish Channel alone the annual crop of phytoplankton ounts to 3600 tons per square mile. Suggestions that plankton might be used directly as human food re revived during the late war after a German report ıt the zooplankton had a nutritive value equal to ıt of the best meat, and the phytoplankton to that rye flour. Investigation showed, however, that ı probable yield from our seas did not warrant the ablishment of a special fishery.

The reducers, the sea's bacteria, are particularly portant to the marine life-cycle. As ZoBell has cently indicated,[1] only a very small part (0·1%) of e primary production of organic matter in the world's eans is removed each year in the form of fish, commer- al algæ, &c.; the remaining residues and waste products plants and animals undergo bacterial decomposition d return in mineralised forms to the sea and atmo- here, where they supply the phytoplankton with the ements, such as nitrogen, phosphorus, and carbon, om which its cell substance is synthesised. Without ıese bacteria the sea floor would soon be cluttered up ith a mass of dead plant and animal remains, and lant life, denied its essential elements, would cease. further important function of aquatic bacteria is the onversion of dissolved organic matter into particulate rganic matter (bacterial cell substance), which animals an utilise. ZoBell himself has found that, given suitable onditions, bacteria can mineralise roughly 70% of the rganic content of sea water and convert 30% into acterial cell substance or intermediate products. It is ebatable, as he points out, whether bacteria are suffi- iently abundant in sea water to constitute an appreciable em in the diet of marine animals, but cumulatively hey are clearly important to the food cycles of both nimals and plants.

A COMPASSIONATE RELEASE

IN July several newspapers reported the case of a oung officer of the Royal Army Medical Corps who vas released from the Service soon after the death of ıis father, with whom he was in partnership. The press eports made it appear that his release was the result of ressure by a Member of Parliament to whom 400 atients were said to have written; and the patients eemed to have been actuated by a belief that this doctor vas the only man who understood a method of treatment ractised by his late father. As may well be supposed, these newspaper reports have caused indignation, especially among those whose tenure of one-man practices did not prevent their acceptance for service during the war. We understand, however, that this officer was not in fact released on the ground that he is professionally indispensable at home: indeed, the local medical war committee, which judges such matters, decided that he was not. The War Office granted him compassionate release, obtainable in extreme cases of individual hardship of financial or domestic nature. Although there has been some relaxation since the end of the war in regard to one-man businesses (and practices) the number of Army medical officers granted compassionate release has been very small—less than 40 out of a total of over 8000 releases.

HOKEY-POKEY PENNY A LUMP

THE present outbreaks of enteric fever recall the profession's ancient quarrel with the uncontrolled sale of ice-cream. It is 67 years since a *Lancet* commission drew attention to the appallingly filthy conditions in which ice-cream was made in the Italian quarter of London.[1] Gone are the days of "penny a lump," but "hokey-pokey" (the Cockney's rendering of the Italian *ecco poco* or "here's a bit") and the outbreaks are still with us. In the interval ice-cream has been credited with ptomaine poisoning, carbolic-acid poisoning, zinc poisoning, and scarlet fever, as well as recurrent outbreaks of enteric. An outbreak of unspecified diarrhœa in Lancashire was traced to premises with "two vessels containing ice-cream in process of manufacture . . . within a yard of a pail-closet; and the fine strainer used for straining the milk and cornflour after boiling was within about four inches of a dolly tub in which were babies' napkins soiled with diarrhœal excreta."[2] Advances in bacteriology served to underline the extent of the scandal. Thus in 1894 the medical officer of health for Islington found in specimens of ice-cream "almost uncountable colonies of *Bact. coli*"[3]; and in 1897 the M.O.H. of Liverpool was impressed with "the marked similarity between plate cultivations of the ice-creams . . . and those of sewage."[4] Only fourteen years ago bacterial counts were found to range from 625,000 to 265,000,000 per c.cm.[5]

In the nineties some local authorities and the larger manufacturers were pressing for regulation of manufacture and distribution, but it was not until the enactment of the London County Council (General Powers) Act of 1902 that the first specific control was imposed. "It is difficult to believe that such categorical exposure of a foul danger to public health should not have been followed by reform until more than twenty years have passed."[6] In 1927 the Ice-Cream Association of Great Britain and Ireland invited the Minister of Health to propose a legal definition of ice-cream and to enforce the licensing by local authorities of all makers and vendors, whose premises should be inspected[7]; but no action was taken. Since then some authorities, and notably Hove, which provisionally adopted the same standard as for pasteurised milk,[8] have shown themselves increasingly alive to the risks. Last year a Ministry of Food order prohibited the admixture, except by licence, of dried eggs, since these may contain salmonella organisms; under the licence makers must pasteurise the mix within two hours of manufacture, and must observe certain other precautions. Otherwise, "it is only when conditions of manufacture are grossly insanitary that the Food and Drugs Act, 1938, is called in to protect the public."[9] Most of us will therefore agree wholeheartedly with the resolution passed by the conference of sanitary inspectors at Westminster on Sept. 5 calling for the compulsory registration of all ice-cream vendors. Until this step is taken no comprehensive plan of control is possible.

THE annual Harveian oration will be delivered at the Royal College of Physicians by Sir Maurice Cassidy on Friday, Oct. 18, at 3 P.M. His subject will be Coronary Disease.

WAR AND THE PUBLIC HEALTH

THIS week the Ministry of Health published a report by Sir Wilson Jameson, the chief medical officer, "*On the State of the Public Health During Six Years of War.*"[1] The enemies facing the public-health services—epidemic disease, malnutrition, and mental stress—were, as the history of 1918 suggested, potentially more menacing than the more usual hazards of battle. The same standard of planning was required to face both these threats to the nation's welfare, and the medical preparations for war were important threads in the larger pattern of national defence. Traditionally this country is supposed to "muddle through" its difficulties, but there are no signs that this was the way at the Ministry of Health. The menace of death in all its forms was faced, an intelligent appreciation reached, and a plan framed which was bold in conception, careful in detail, and yet elastic enough to meet the changing needs and fortunes of war. When it was put to the test there were of course failures and mistakes, but all in all the offensive-defensive campaigns waged by the Ministry and its satellites in town and country were as successful as those of the fighting Services.

It was soon realised that intelligence, in the military sense, was a first essential. Even before September, 1939, an intelligence section was established at the Ministry to provide information not only for the civil population but also for the military Services. During the war itself, field investigations on epidemic illness and sample surveys of patients in the E.M.S. hospitals and of minor sickness among the civil population kept the Ministry staff well informed. Gloomy if reasoned forecasts of casualties evoked a major effort in building up the staff, equipment, and organisation of the Emergency Medical Service. With the number of injured mercifully less than had been anticipated, the switch of the service to the less dramatic but none the less useful forms of medical care was rapid and effective. Experience in the blitz with the nation-wide civilian defence casualty organisation, and in particular the ambulance service, showed the advantages of large-scale administration in this field. Into the fight were called the auxiliary services of the laboratory. Blood-transfusion was widely used, and, as the report says, its practice "has increased prodigiously and will increase still further. Transfusion is a procedure directed to the treatment of disorders of the circulation. There is little in medicine on which the study of the circulation does not impinge and it is for this reason that the advances stimulated by the war in this field have had, and are likely to have more, profound repercussions in many fields of civilian medical practice." The Emergency Public Health Laboratory Service spread a net of laboratories, well-staffed and adequately equipped, over the whole country. These undertook not only routine diagnostic and public-health work but also valuable field researches on epidemic diseases.

While the responsibility for feeding the people lay elsewhere, the Ministry of Health busied itself with surveys of the essential foods. Insufficient diet, particularly when combined with overwork and overcrowding, brings in its train the risk of an increasing incidence of tuberculosis, and the preventive efforts of local-government doctors were redoubled. The hardships of war bear most heavily on expectant mothers and young children; their defences were strengthened by dietary supplements. The traditional association of Mars and Venus brought a rising incidence of venereal diseases, leading the Ministry to discard its last Victorian inhibitions and to embark on a virile and aggressive publicity campaign. Another enemy, insidious but disabling, was the anxiety and fear engendered by the onslaught on the civil population; it was countered by the ps logical selection tests and welfare work in industry, psychiatric treatment in special E.M.S. clinics.

What were the results of this campaign? The ulti arbiter must be the account of the nation's heal the vital statistics of the war years, for "facts are that winna ding." The infant and child mort rates are particularly sensitive indicators of social being; despite the loss, by enemy action, of the of 7000 children under the age of 15, and an increa accident deaths through war conditions, the mean death-rates in the three five-year groups under 15 below the rates for any year before 1939. New re for the second and third years of life were set up in 19 and new low levels for neonatal, infant, and mortality in the first ten years of life were attained 1944. The stillbirth-rate declined continuously th out the war, while successively lower records for mortality were established in 1940, 1942, 1943, and 1 Another index to national health is the tubercul death-rate. After a disquieting rise in 1939–41, t pre-war downward trend was resumed, to reach a ne low-level record in 1944. In the field of epidemic di the major triumph was the immunisation camp against diphtheria; in 1944, deaths were less than one third of the pre-war average, although this essentially preventable disease still caused more deaths than enemy bombs. Diseases such as typhoid fever, which have been expected to spread in the disturbances an dirt of bombed cities, were held in check, but there w an increase in scabies, food poisoning, and dysentery due, no doubt, to the difficulties of personal and culinary hygiene. Field research, stimulated by an awaken of the community's social conscience, uncovered t importance, as causes of disability, of rheumat anæmia, and accidents in the home; and the need special care for the aged. These are not new proble but their extent was highlighted by the statistics wh these studies produced.

The advantages of nation-wide organisation in preven tive medicine have been fully demonstrated. In the Health Service these advances can be consolidated administrative efficiency is tempered with humanity.

FOOD FROM THE SEA

IN normal times about thirteen million tons of is removed from the oceans of the world every Of this catch some is consumed directly, either fr preserved, or canned; but a large part goes to the ma of over a million tons of fish meal, which contribute indirectly to human diet through the nourishment farm animals and poultry; and the Antarctic whal industry produces upwards of half a million tons of of which a quarter of a million tons is converted eating. In the years before the war the average ann consumption of fish in this country was 16½ lb. per hea this was two or three times the consumption in France Germany, or the U.S.A., but only half that in Jap and possibly a tenth that in Norway. Measured by labou fish are a cheap source of first-class protein. There is wide variety of edible species, all highly nutritive a rich in minerals—the iodine content, for example, 50–200 times as great as that in any other food, wh that of calcium and phosphorus is as high as in bee Moreover, fish are available all the year round, and ne techniques of freezing enable such fatty fish as th herring, which vary with the seasons, to be distributed at their best throughout the year. Perhaps we do n benefit fully from the bounties of the sea. Certainl long usage has clouded our appreciation of this uniq harvest for which no field must be ploughed or cultivated, no seed sown, and no stocks tended.

As on land, animal life in the sea depends either directly or indirectly on plant life. This is found mainly

e plankton, of which there are three groups— cers, consumers, and reducers. The producers rise largely the chlorophyll-bearing diatoms and which by solar energy build up organic matter inorganic nutrients in the water. The consumers oplankton feed on the living or dead matter of this plankton or its metabolic products, and are in turn umed by such fish as herring, pilchards, sprats, erel, and, curiously enough, one of the world's st mammals—the rorqual whale. Much of the g or dead plankton falls to the sea floor, where it is by the bottom fauna, including worms and shell- which in their turn form the food of the bottom- g fish. The amount of plankton is very large, being ially rich in some Polar areas, but varies from one n to another; it has been estimated that in the ish Channel alone the annual crop of phytoplankton unts to 3600 tons per square mile. Suggestions that plankton might be used directly as human food revived during the late war after a German report the zooplankton had a nutritive value equal to of the best meat, and the phytoplankton to that ye flour. Investigation showed, however, that probable yield from our seas did not warrant the blishment of a special fishery.

he reducers, the sea's bacteria, are particularly ortant to the marine life-cycle. As ZoBell has ntly indicated,[1] only a very small part (0·1%) of primary production of organic matter in the world's ns is removed each year in the form of fish, commer- algæ, &c.; the remaining residues and waste products lants and animals undergo bacterial decomposition return in mineralised forms to the sea and atmo- ere, where they supply the phytoplankton with the nents, such as nitrogen, phosphorus, and carbon, n which its cell substance is synthesised. Without se bacteria the sea floor would soon be cluttered up h a mass of dead plant and animal remains. and nt life, denied its essential elements, would cease. urther important function of aquatic bacteria is the version of dissolved organic matter into particulate anic matter (bacterial cell substance), which animals utilise. ZoBell himself has found that, given suitable ditions, bacteria can mineralise roughly 70% of the anic content of sea water and convert 30% into terial cell substance or intermediate products. It is atable, as he points out, whether bacteria are suffi- ntly abundant in sea water to constitute an appreciable n in the diet of marine animals, but cumulatively y are clearly important to the food cycles of both mals and plants.

A COMPASSIONATE RELEASE

N July several newspapers reported the case of a ng officer of the Royal Army Medical Corps who s released from the Service soon after the death of father, with whom he was in partnership. The press orts made it appear that his release was the result of ssure by a Member of Parliament to whom 400 tients were said to have written; and the patients med to have been actuated by a belief that this doctor s the only man who understood a method of treatment ctised by his late father. As may well be supposed, se newspaper reports have caused indignation, ecially among those whose tenure of one-man prac- es did not prevent their acceptance for service during war. We understand, however, that this officer s not in fact released on the ground that he is profes- nally indispensable at home: indeed, the local medical r committee, which judges such matters, decided that he was not. The War Office granted him compassionate release, obtainable in extreme cases of individual hardship of financial or domestic nature. Although there has been some relaxation since the end of the war in regard to one-man businesses (and practices) the number of Army medical officers granted compassionate release has been very small—less than 40 out of a total of over 8000 releases.

HOKEY-POKEY PENNY A LUMP

THE present outbreaks of enteric fever recall the profession's ancient quarrel with the uncontrolled sale of ice-cream. It is 67 years since a *Lancet* commission drew attention to the appallingly filthy conditions in which ice-cream was made in the Italian quarter of London.[1] Gone are the days of "penny a lump," but "hokey-pokey" (the Cockney's rendering of the Italian *ecco poco* or "here's a bit") and the outbreaks are still with us. In the interval ice-cream has been credited with ptomaine poisoning, carbolic-acid poisoning, zinc poisoning, and scarlet fever, as well as recurrent outbreaks of enteric. An outbreak of unspecified diarrhœa in Lancashire was traced to premises with "two vessels containing ice-cream in process of manufacture . . . within a yard of a pail-closet; and the fine strainer used for straining the milk and cornflour after boiling was within about four inches of a dolly tub in which were babies' napkins soiled with diarrhœal excreta."[2] Advances in bacteriology served to underline the extent of the scandal. Thus in 1894 the medical officer of health for Islington found in specimens of ice-cream "almost uncountable colonies of *Bact. coli*"[3]; and in 1897 the M.O.H. of Liverpool was impressed with "the marked similarity between plate cultivations of the ice-creams . . . and those of sewage."[4] Only fourteen years ago bacterial counts were found to range from 625,000 to 265,000,000 per c.cm.[5]

In the nineties some local authorities and the larger manufacturers were pressing for regulation of manufacture and distribution, but it was not until the enactment of the London County Council (General Powers) Act of 1902 that the first specific control was imposed. "It is difficult to believe that such categorical exposure of a foul danger to public health should not have been followed by reform until more than twenty years have passed."[6] In 1927 the Ice-Cream Association of Great Britain and Ireland invited the Minister of Health to propose a legal definition of ice-cream and to enforce the licensing by local authorities of all makers and vendors, whose premises should be inspected[7]; but no action was taken. Since then some authorities, and notably Hove, which provisionally adopted the same standard as for pasteurised milk,[8] have shown themselves increasingly alive to the risks. Last year a Ministry of Food order prohibited the admixture, except by licence, of dried eggs, since these may contain salmonella organisms; under the licence makers must pasteurise the mix within two hours of manufacture. and must observe certain other precautions. Otherwise, "it is only when conditions of manufacture are grossly insanitary that the Food and Drugs Act, 1938, is called in to protect the public."[9] Most of us will therefore agree wholeheartedly with the resolution passed by the conference of sanitary inspectors at Westminster on Sept. 5 calling for the compulsory registration of all ice-cream vendors. Until this step is taken no comprehensive plan of control is possible.

THE annual Harveian oration will be delivered at the Royal College of Physicians by Sir Maurice Cassidy on Friday, Oct. 18, at 3 P.M. His subject will be Coronary Disease.

LENGTH OF STAY IN HOSPITAL

Frances Gardner * L. J. Witts
M.D. Lond., M.R.C.P. M.D. Manc., F.R.C.P.
From the Nuffield Department of Clinical Medicine, Radcliffe Infirmary, Oxford

It has recently been suggested that the need for hospital beds could be diminished by the provision of better facilities for outpatients or by the building of hostels for patients who require only one or two nights' accommodation for investigation or other purposes (*Lancet* 1943, Lister 1945, Morgan 1945, Nelson-Jones 1946). Others have urged the creation of special wards or hospitals for illnesses which cannot be classed as incurable but nevertheless require protracted or specialised treatment; rheumatoid arthritis, peptic ulcer, ulcerative colitis, and nephritis have been put in this category.

With these suggestions in mind, we have recently analysed a year's admissions to a medical ward of 21 beds, 10 male and 11 female. The ward is essentially a diagnostic and research unit. There was great pressure on our beds during the year under review, as the Radcliffe Infirmary, which serves a population of 250,000, had at that time only 80 general medical beds, and there were no other medical beds in the area except in cottage hospitals or hospitals of the poor-law type. The ward was protected from the full pressure of the competition for beds by the fact that it was " on take " on only one day a week. In other words, though containing one-quarter of the medical beds, it admitted only one-seventh of the emergencies which came into the medical side of the hospital. In spite of this, over 30% of the admissions were emergencies.

During the period under review 180 men and 175 women were admitted to the ward. Though the total number of patients was 355, the total number of admissions was 440, because 28 patients were readmitted on one or more occasions during the year. The average proportion of occupied beds was 19 out of 21; 626 (8%) of the available bed-days were wasted. This wastage was partly due to temporary war-time conditions —beds had to be kept empty and available for D-day casualties—but it was also an inevitable result of the system of emergency admissions. All emergency cases must be admitted on the day of "take." It therefore behoves the house-officer to arrange the discharge of patients so that some beds are empty on the appropriate day, and it is impossible to estimate with accuracy the number of beds required.

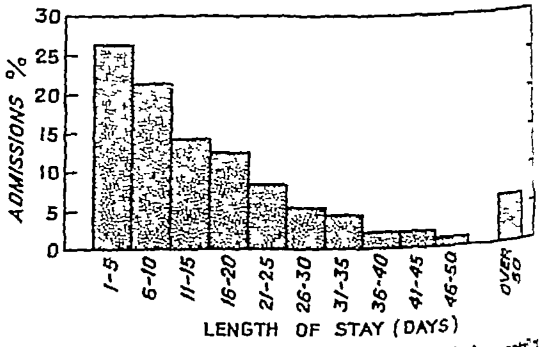
The average duration of stay in hospital was about 16 days, but the accompanying figure shows that this average figure is somewhat misleading. The largest fraction of patients stays the shortest time in hospital, and the proportion of patients remaining in hospital steadily declines as the period of treatment increases. The length of stay in 26% of admissions was less than six days, and in nearly 50% of cases the patient was discharged within eleven days of entering hospital. At the other extreme is the group of 24 patients who were in hospital for more than fifty days. They accounted for 1772 bed-days, which may be roughly expressed by saying that 5% of the admissions accounted for 25% of the bed-days. An analysis of the whole series of patients will be published by us elsewhere, and we deal below only with the two extremes of short and long admissions.

SHORT ADMISSIONS

The reasons for inpatient treatment of the patients who stayed less than six days are shown in table I: 66 patients in this group were responsible for 113 sions; 27 were admitted as emergencies for the tre of acute illness, and 10 of these died shortly admission, the remainder being either discharged transferred to other hospitals within a few days. the other patients were admitted from the waiting- 17 patients were admitted for follow-up examinat coming either from other areas or from remote p of the surrounding counties; 11 patients unde treatment with thiouracil were repeatedly adm for estimation of basal metabolic rate, a for 54 short admissions; 3 patients were res sible for 5 admissions for blood-transfusions; the remaining 8 patients were admitted for investigations.

In all, 39 patients from the waiting-list were respo for 86 admissions and 151 (2%) of the bed-days. stays in hospital of this kind undoubtedly give ris some administrative problems. They tend to smooth routine in a busy medical ward. Most of patients are in fair health and often in full employme and they may resent the small restrictions which must imposed in a hospital ward. Moreover, the amount nursing time devoted to them seems out of p to their needs. These are the considerations have led to the suggestion that patients of type might equally well be treated in the outpatie department.

It is possible to divide the short-stay patients admitt from the waiting-list into two groups. The first those who require a bed overnight, either because examination, such as cholecystogram or basal metabol is to be carried out fasting, or because the patient li too far away to travel to and from hospital in one d Admissions of this kind can be arranged to suit t convenience of the patient and the hospital, and pati should rarely need to stay more than one night. other group is constituted by patients who come i a short treatment, such as transfusion or paracent and require a bed for about twenty-four hours. admissions can also be planned ahead, though not so f ahead as the first group, and the patients are more li to overstay the expected time because things go wro The division is not hard and fast, for some investigatio such as lumbar puncture and gastroscopy, entail a reco period. Follow-up patients come into both grou Indeed, it is only necessary to make an analysis of t kind to realise that the antithesis between outpatie and inpatients is false; rather should we think of t key hospital as a centre for diagnosis and special trea ment, which may or may not require the patient admission.



Frequency histogram to show the percentage of admissions ent different lengths of stay in hospital.

The need for short stays in hospital grows steadi with advances in diagnosis and treatment. Period transfusions for refractory anæmia, estimation of the metabolism of patients receiving thiouracil, and desensitisation to liver of patients with pernicio

ıia are examples of recent additions to the list. sport to and from hospital inevitably presents derable difficulties in a rural area, and often stigations arranged for outpatients would be more ditiously and conveniently completed if a night's ng could be provided. Far from using outpatient ties inadequately, we believe we are using them cess. It would be kinder to admit to hospital some e patients who now undergo tedious and exhausting stigations as outpatients, but shortage of beds made it impossible. It is probably true that when possible to consider the comfort of the patient more ly the demand for short-term accommodation will tly increase.

LONG ADMISSIONS

he reasons for prolonged inpatient treatment in the atients who were in hospital longer than fifty days shown in table II. Many of them were gravely ill, and them had died by the time of the follow-up, from one wo years later. The largest fraction was made up 4 patients who underwent surgical treatment after ical investigation; 2 patients were kept in hospital ıuse they were the subjects of research, and 2 others ıuse it was difficult to find accommodation for them where—a woman needing special X-ray therapy, a boy dying of lymphosarcoma. The remaining re a heterogeneous group who had in common only fact that they required prolonged medical treatıt. In retrospect it appears that only 3 of these patients (rheumatoid arthritis, nephritis, and ulcerative tis), accounting for 260 (less than 4%) of the available l-days, could have been referred to a long-stay hosıl, if such had been available.

LE II—REASONS FOR STAY IN HOSPITAL LONGER THAN 50 DAYS

eticulosis	1	*Research*	2

A different picture was obtained when we inquired into fate of some of the patients with chronic diseases who yed in hospital less than fifty days. In table III have summarised the data for all cases of peptic ulcer, umatoid arthritis, ulcerative colitis, and nephritis this group. Many of these patients had been incapacitated for more than a year before admission to hospital. They remained in hospital only three weeks on the average and then were discharged home, sometimes with a short interval in a convalescent home or cottage hospital. The results of treatment have been strikingly unsuccessful: 8 of the 12 patients have required readmission, and only 6 of them are back at work, from one to two years later. Therapeutic failure may be inherent in the nature of these diseases, though one would not judge so from reading textbooks of medicine and treatment. A more justifiable comment would be that the diagnostic hospital is not adapted to the treatment of subacute and chronic illness. Patients with peptic ulcer and similar diseases are not admitted unless there is some complication, such as vomiting, hæmorrhage, or intractable pain; and, when they are admitted, they are often discharged before treatment could be effective. This is largely the result of shortage of beds, but there are also reasons which must be included under the heading of psychological attitudes and motivation. Both diagnostic and teaching hospitals are driven to regard themselves as sorting- and clearing-houses, and the tempo is too swift for great interest to be taken in protracted therapeutic procedures.

DISCUSSION

Short-stay admissions are important because of their increasing frequency, long-stay admissions because they account for a relatively high proportion of occupied beds. Both are of particular interest to the outpatient physician, who has the hard task of selecting patients for admission. We do not find that patients who could be dealt with as outpatients are being admitted to hospital unnecessarily. On the contrary, the work of the outpatient department would be easier if some of the patients now investigated there were admitted to hospital for one or two nights. We therefore agree with Rock Carling and Power (1943), who pointed out that the existence of a highly organised and efficient outpatient service is likely to increase rather than diminish the demand for beds. Our main criticism of the present arrangements for admission is that too much responsibility is left with house-officers and administrative staff, and that more care might still be taken in selecting patients from the waiting-list and in correlating the outpatient and inpatient work of the unit. The rival claims of medical urgency, social stress, and efficient employment of the ward need balancing, and doctor, secretary, and almoner should combine in the task. Whenever a patient fails to enter hospital when written for, an inquiry should be made by the almoner.

Our review has less bearing on the problem of long-stay hospitals. There is little doubt that the potential demand for accommodation for long-stay cases is very

TABLE III—ANALYSIS OF PATIENTS WITH CHRONIC ILLNESS WHO STAYED IN HOSPITAL LESS THAN 50 DAYS

Disease	Patients	Average duration of stay in hospital (days)	Average duration of incapacity (months)		Patients readmitted
			Before discharge	After discharge	
Peptic ulcer	7	18	24	12	4
Rheumatoid arthritis	3	22	14	13	2

Nephritis	1	18	None	22	1
Total	12	21	12*	14	8

* This figure represents the mode or usual duration of incapacity, and not the average, which is distorted by a few very chronic cases.

great. It could be better assessed from an analysis of the records of outpatient clinics and X-ray departments than from a study of this kind. With the present shortage of beds, the physician seeing outpatients rarely attempts to secure admission for cases of peptic ulceration and rheumatoid arthritis; and, when such patients are admitted, they are referred within a few weeks for treatment in convalescent hospitals, their own homes, or the outpatient department. All that we can say is that provision of hospitals for prolonged treatment of these patients would not greatly relieve the pressure on beds required for purposes of diagnosis. By the same logic it should not reduce the variety of clinical material in the teaching hospitals. Any measure which entirely removed chronic illness from the teaching hospitals would have a lamentable effect on the training of nurses and students and on the advancement of knowledge.

The present tendency to specialisation in medicine, both by individuals and by departments, is continuously raising obstacles to the communication of ideas and to the integration of treatment. Sickness is not just a production job which can be broken down into separate elements and treated by the methods of modern mass manufacture. It is a personal and individual problem, and the operative proverb is "too many cooks spoil the broth," and not "many hands make light work." In a previous paper from this department, the need for continuity in treatment was heavily underlined (Brown and Carling 1945). The community hospital has a corporate spirit, which might be weakened by overelaboration of function and loss of adaptability. What is required today is not a further specialisation of purpose but an internal reconstruction. At present the medical beds in hospitals in this country are usually divided into a series of separate units or firms which work more or less independently and whose chiefs have a great sense of pride and property in their charge. This traditional arrangement is steadily becoming less adapted to the needs of the patient and the medical student. It is suggested that the time has come for a division on more functional lines.

If we think in terms of patients, we find that we have to deal with emergency admissions, usually of acutely ill patients; short-stay admissions from the waiting-list of patients who are not ill and do not require much nursing; and medium- and long-stay admissions. If we translate these demands into bricks and mortar, we shall design a medical unit which consists of three sections: (1) the diagnostic and treatment unit, which would correspond very closely with our present ward; (2) the short-stay ward or hostel, which would cost half as much per bed-week; and (3) the long-stay ward, where the emphasis would be on treatment and research. All these three adjoining sections would be the field of work of one team of nurses, technicians, assistants, and physicians, whose outpatient department would be on the same floor or at least connected by direct lift. The optimal size of a unit of this kind would probably be about 75 to 100 beds. With less beds than this the subsections for the two sexes would become too small for effective working, whereas a larger number of beds would be too many for an integrated unit with a life and personality of its own.

For several reasons we are opposed to the suggestion that special hostels should be provided for short-term admissions of every kind, and that these hostels should be separate from the wards of the hospital. The clinical field is already divided into too many separate compartments, and we do not want to split it up further. Most of our short-term patients enter for follow-up or for special treatment, and they like to come back to the ward where treatment was started and where they feel that their case is understood. The introduction of hostels would be only too likely to bring its own crop of psychological and administrative problems. Even the recurrent type of admission is sometimes inadequ supervised, as the period of observation extends several generations of house-officers. Lack of supervision is obviously undesirable, and it may dangerous in protracted treatment with thiour sulphonamide drugs. Recurrent admissions are essent part of the follow-up work of the ward. Evidence the value of following up all patients who have admitted to hospital has been published from this dep ment (Brown and Carling 1945). We believe that follow-up should be separated from the diagnostic of the outpatient department, and that it should be out in close proximity to the ward. The same tea senior medical officer, secretary, and almoner shoul responsible not only for the selection of cases waiting-list but also for the general follow-up and supervision of recurrent admissions.

SUMMARY

We have analysed 440 consecutive admissions medical ward which is essentially a diagnostic research unit.

Short-stay cases form a high proportion of the ad sions, but there is no evidence that the number coul have been reduced without detriment to the p by provision of better outpatient facilities.

Patients who were in hospital for more than fifty account for only 5% of the admissions but 25% of bed-days. More than half of them were patients eventually required surgical treatment. Only 3 pati in this group, accounting for less than 4% of the days, could have been referred to a long-stay hos or a centre for special treatment.

Special accommodation for short-stay and long cases would have released only 6% of the bed-days, therefore would not have relieved to any great ex pressure on the beds required for diagnostic purpos

Patients who might be expected to need pro treatment seem to have been admitted to hospital wi some reluctance owing to shortage of beds, and were often discharged prematurely. The results treatment in this group were strikingly unsucc The need for long-stay accommodation could be estimated from an analysis of outpatient and X-ray re than from a study of this kind. It is undoubtedly gr

The common practice of splitting the medical be a hospital into small autonomous units does not ideal. They should be arranged in functional grou to meet the needs of the different types of admiss

We are indebted to Miss I. F. Beck for much help in tr patients and analysing the data. For suggestions for ho design we have obviously borrowed from the ideas of Sir Rock Carling.

"Medical schools are charged with the responsibility admitting not those who say, however earnestly, that want to study medicine, but those judged to have the vation, industry and ability for the pursuit of a profes involving the health and the lives of the people who seek medical aid in the years to come. The admissio students lacking the qualifications for a medical car wasteful and harmful no matter how much the student thinks he would like such a career. The cost of failure medical school, in money and time and work and disapp ment, is so great that extreme care must be exercised the selection of students, even if enrolments decrease. Fr man enrolments in 1946 will exceed 5500 mainly becaus the many veterans admitted . . . about 60% will be in category. . . . About 12% are women."—*J. Amer.* *Ass.* August 17, p. 1355.

A NEW HEALTH SERVICE

THE DESIGN IN SOUTHERN RHODESIA

rksome and circuitous as the methods of democracy seem to harassed administrators, in the long run the ts are more stable and permanent. Progress in public h must be built increasingly on the basis of an informed ic opinion and intelligent public coöperation. There a democratic country no short cut."

ɔn this principle the commission which has been ing into the health services of Southern Rhodesia [1] m to affirm that the colony has now passed the r stage and must therefore proceed by democratic ıds. In its recommendations it has sought to freedom of action and choice for doctor and patient to free the citizen from the fear of financial rassment through ill health, while yet leaving him oulder some responsibility; and to intervene to le services only where they are not already being ntly provided at a reasonable cost.

introduce a national health service in Southern esia may be at once more difficult and easier than s country, for in the colony there is already a govern- medical service and all the European hospitals t one are government hospitals. Some of the more us administrative snags are thus absent. But ıern Rhodesia has the heavy responsibility of a large npoverished African population, who will be able to ibute only a small part of what must be spent on . The commission firmly opposes any attempt to expenditure on African health to African revenue.

e commission is equally convinced that health prob- are indivisible, and that, though methods of dealing each section of the population may vary, a national ce must cover everybody. It therefore proposes for all races hospital treatment, maternity and X-ray ment, and laboratory services should be provided by State. And though the individual is to be left to for his general practitioner, his dentist, his surgical ance, and his drugs, his burden is to be adjusted to nancial strength: the maximum he will be asked to for these services in any one year will range from £2 me of £100) to £55 (income £2000). All amounts e this will be met from a national medical fund on uction of the doctor's receipted account. The imum covers the doctor's bill for a whole family, h means that married men with children will probably heavier claims on the fund than bachelors or less couples. No contributions have to be paid, t of course from general taxation. Patients who do wish to accept the salaried consultant staff at the itals must pay the full rates at the hospitals as well heir private doctor's fee. A medical committee of rol, on which laymen as well as doctors would be esented, will be set up to investigate cases in which ssive visiting or excessive prescribing is suspected.

ıe commission recommends the creation of a separate ırtment of health directly responsible to the minister ıealth. It also proposes the establishment of a ɔnal health board and the division of the colony into regions with further subdivisions of areas which ld approximate to the present native districts. The d would have nine members, including representatives he regions, the secretaries for health and native rs, and two doctors. Its functions would be advisory policy-making and it would have the duty of drawing national health plan from the plans submitted by the ɔns. Each of the regions would in turn have its ıcil, again an advisory and planning body, and in region and area there would be a medical officer of th in charge of the State health services.

ssuming that right of private practice will be with- vn, the following salaries are suggested for doctors in new service: secretary for health, £2250; consultants,)0–£2500; directors of public health or research,)0–£2000; regional M.O.H.S, £1500–£1750; area H.S. £750–£1500. The general scale for government ical officers (£750–£50–£1500) will, it is felt, not attract doctors into the service but retain them in it.

The larger local authorities which are able and willing to carry out environmental services should continue to do so and should be given financial help to expand them. But in general the smaller municipalities should look towards further expansion of their health services as integral parts of their areas. Similarly, though the State will assume responsibility for the treatment and prevention of venereal diseases and institutional maternity work, municipalities and voluntary organisations will be encouraged and helped to continue any clinics which they are running. The mines and mission hospitals for natives will also be subsidised.

The commission also open the way to a great expansion of the preventive services of the colony with proposals that a nutrition council and a research council should be set up. The members included Prof. C. F. M. Saint, M.S. (chairman), and Dr. T. G. Burnett.

INFECTIOUS DISEASE IN ENGLAND AND WALES

WEEK ENDED AUGUST 31

Notifications.—Smallpox, 0; scarlet fever, 744; whooping-cough, 1976; diphtheria, 262; paratyphoid, 44; typhoid, 27; measles (excluding rubella), 1565; pneumonia (primary or influenzal), 279; cerebrospinal fever, 41; poliomyelitis, 21; polio-encephalitis, 4; encephalitis lethargica, 0; dysentery, 74; puerperal pyrexia, 131; ophthalmia neonatorum, 98. No case of cholera, plague, or typhus was notified during the week.

The number of service and civilian sick in the Infectious Hospitals of the London County Council on August 28 was 854. During the previous week the following cases were admitted: scarlet fever, 46; diphtheria, 17; measles, 42; whooping-cough, 43.

Deaths.—In 126 great towns there were no deaths from scarlet fever, 1 (0) from enteric fever, 2 (0) from measles, 9 (0) from whooping-cough, 5 (0) from diphtheria, 31 (5) from diarrhœa and enteritis under two years, and 6 (0) from influenza. The figures in parentheses are those for London itself.

Halifax reported the fatal case of an enteric fever.

The number of stillbirths notified during the week was 277 (corresponding to a rate of 31 per thousand total births), including 40 in London.

In England Now

A Running Commentary by Peripatetic Correspondents

"OF course," said the German Mayor, "we quite understand that at the end of an unexpectedly victorious war you must be a little disorganised and that your Military Government is a temporary affair, but when is the real government coming out?" This was said some four months after the end of the war. Nobody would think of saying it now, I fancy, but with the Dodo in *Alice* might talk about the Caucus-race. You remember?

"What is a Caucus-race?" said Alice. "Why," said the Dodo, "the best way to explain it is to do it." First it marked out a race-course in a sort of a circle; then the party were placed along the course here and there. They began running when they liked, and left off when they liked, so that it was not easy to know when the race was over. . . . Then the Dodo suddenly called out "The race is over, everybody has won, and everybody must have prizes." Unfortunately for us the prizes on this occasion are given jointly by the British taxpayer and the German population. Since the German population is already subsidised by the taxpayer to the tune of eighty million a year, our administration of Germany bids well to become the most expensive that bureaucracy has ever succeeded in foisting on any people. Not that there are not many well-qualified and devoted administrators in the service; there are. To them the restrictions inevitably imposed by the uncertainty of international affairs, limiting as it does their planning and organisation, must be irksome. There are however far too many to whom the service means a cushy job at a big salary without expenses. To these must be added the large group of people, unsettled by the non-recurring opportunities of the war, who are unable to reseat themselves in normal civilian life but find a haven in the peculiar conditions that obtain in Germany.

It is a little galling to find that a Control Commission driver gets (I do not say earns) a bigger salary than a captain, R.A.M.C., and that an ex-corporal can return to an almost non-existent job at a salary of eight to ten pounds a week with negligible expenses.

There are welcome signs that Authority is not unaware of all this and is taking steps to remedy the defects. Much harm has already been done to our prestige over here, and it is high time to restore it to the position it held at the end of the fighting.

It is perhaps unfortunate that this period should coincide with the arrival of the first families who will absorb a great deal of accommodation sadly needed by the Germans themselves. This new influx is perhaps the most unpopular measure that we have yet conceived. Touching, as it does, only a fragment of the army out here it is debatable whether the atmosphere of artificial comfort provided for the families will do anything but estrange both the Germans and a large number of British as well. What we are seeing in Germany is not what we mean by the "British Way of Life." It is to be hoped that those wives who do come out will realise how important it is that they should bring with them the influences that go to make a British home.

The Control Commission has to face difficulties as great as any that have faced our colonial administrations. In the past, selection for the Colonial Services has been stringent, and the results usually good. Should not the same principle be applied to this, the newest of all our administrative services?

* * *

Mumpsimus, "a traditional custom obstinately adhered to however unreasonable it may be." Woe is me! My conscience pricks badly. Every day I meet a myth or a mumpsimus about the hospital and do nothing about it: it does no harm, I murmur, and let it pass. What of the nursing woman-hours wasted; what of discomfort and indignity endured in vain?

I speak here with added authority. Only last week I myself was sigmoidoscoped. The appointment was for 11 A.M. At 5 A.M. I was rudely awakened by the clank of the loaded trolley and my opening eyes beheld a gallon-measure full of soapy water and a large bucket full of mackintoshes. The actual washout was only slightly uncomfortable, the fluid gravitating in and in and out of my empty rectum without let or hindr when it was over I fell asleep again. At 8.30 I ate a b breakfast, at 9 allowed my lower bowel to empty a its wont, then wrote letters till my hour was come.

Now why, oh why that eerie ceremony at dawn? the nursing staff feel they ought to prepare their pat for parade? Must the rectal mucosa have its wash- brush-up, spit-and-polish? Should we not declare mumpsimus, reasoning that in six hours anything happen, and it doesn't really matter if it does?

* * *

Some griefs are med'cinable, quotes an advertiser discussing the troubles which cause nervous indi and the merits of a dietary product in its relief. very true, no doubt, but why press Cymbeline into vice? Medicinable means medicinal, capable of he and not medicable, capable of being healed. And w possesses this power of healing? Clearly grief, or s griefs. Grief is the healer, not the to-be-healed. W we wait for Belarius to make this abundantly clear?

Great griefs, I see, medicine the less; for Cloten
Is quite forgot. (IV, ii, 244.)

But let Imogen speak for herself. On receiving h husband's letter, she exclaims:

You good gods,
Let what is here contain'd relish of love,
Of my lord's health, of his content,—yet not
That we two are asunder; (let that grieve him:
Some griefs are med'cinable; that is one of them,
For it doth physic love)—of his content,
All but in that! (III, ii, 28.)

No other play has all these three: medicinable, a the verbs to medicine and to physic. To medicine occ only once more, in Iago's terrible boast:

Not poppy, nor mandragora,
Nor all the drowsy syrups of the world,
Shall ever medicine thee to that sweet sleep
Which thou owedst yesterday. (III, iii, 330.)

Some griefs, we learn, are medicinable; Othello's not one of them:

Fell sorrow's tooth doth never rankle more
Than when it bites, but lanceth not the sore.
(Richard II, I, iii, 297

* * *

The psychiatrist went as a bicycle to the ship's fa dress dance, the surgeon as Ohm's law, and I— everyone said that I, complete with stomacher a periwig, looked the living image of Archimedes imm diately before attaining notoriety in the first M.B. T is everyone except the capstan-minder's mate, who f some reason was judging the competition.

He had not liked me from the day I had pointed o to the captain that the sprockets were rusty. I sh here explain that the Sea Salt's Code shows clearly t simply the inevitable consequences of rusty sprock Just as Q.E.D. ends all theorems everywhere, whe anything has been proved or not, so the rule that o rusty sprocket equals three small keelhauls—"sma indicating that the thin end of the boat be used for t operation—holds on all ships, on all the ponds of t earth. The capstan-minder's mate, one might say, h out-sprocketed himself, in that not only were t 15 sprockets rusty, but 7 more were so sclerosed as to b useless. I am surely not to blame because the wretch fellow was under water for most of the time between t equator and latitude 754. This should be no reason f deliberately mistaking me for a hors-d'œuvre var and giving the prize to the psychiatrist, whose ty were not even pumped up.

* * *

It was Sunday morning and I had to visit an outly hospital. My daughter, aged eight, came along and s she had become rather bored during the car ride I to her in to see the children's ward. While I stood talki to sister one of the nurses showed her around. ". . . a this little boy fell off a ladder. . . . This little girl has a ver bad cough." And then my daughter, wanting to sho an intelligent interest, was heard to say: "I wonder— have any of them got V.D.?" I understand that the poster showing a bereaved widow was withdraw because it depressed people. On my part, I should to raise an embarrassed voice to ask the Ministry o Health to stop *their* poster campaign!

Letters to the Editor

ALMROTH WRIGHT AND ANTI-TYPHOID INOCULATION

ı,—Sir Almroth Wright has just passed his eighty- birthday and the *Times* has reminded us that this is also the fiftieth anniversary of the beginning of vork on prophylactic inoculation against typhoid . That work was an outstanding landmark in the ry of medicine, not only because of its immense tical results but because it demonstrated the possi- of evaluating the changes in an inoculated person's d which result from successful immunisation. From time immunisation ceased to be a hit-and-miss edure.

right himself, in his first paper on the subject, was ful to point out that the idea of using prophylactic unisation against typhoid fever (and also the use of n-living vaccine for the purpose) had come to him ı Haffkine who had applied a similar procedure in bating cholera in India. It is, however, beyond ot that the whole credit for working out anti-typhoid unisation, and for getting it adopted in the British y in spite of considerable opposition from some in places, belongs to Wright.

ı view of this it is surprising to read in Dr. Guthrie's at *History of Medicine* that

> "During the South African War of 1899–1902 typhoid ver was a more formidable foe than the enemy and counted for twice as many deaths as his weapons. In e Great War typhoid fever was relatively rare and, even in e most unhealthy centre, that of Gallipoli, the incidence as very small, and the enormous improvement was most entirely due to the success of anti-typhoid inocula- on. This happy result may be traced to the labours of ıe man—Sir William Boog Leishman (1865–1926), a edical graduate of Glasgow.[3]"

, in a later sentence:

> "Along with Sir Almroth Wright, who preceded him as rofessor of Pathology in the Army Medical College at etley, and whose name is closely linked with the discovery vaccine therapy, Leishman set himself to devise a system inoculation against typhoid. . . ."

he reference given in the above quotation is to e 1058 of Sir Harold Scott's *History of Tropical licine*, but it is difficult to see how the relevant ence on that page can support Dr. Guthrie's state- ıt. It reads as follows:

> "In 1897 he (Leishman) returned to England and was osted to the Victoria Hospital, Netley, as Medical Officer. etley was at that time the headquarters of the Army edical School, later transferred to Millbank as the Royal rmy Medical College. Dr. (later Sir) Almroth Wright as then Professor of Pathology and Leishman gained sperience under him and together they inaugurated oculation against typhoid fever. He also assisted Wright ı his work on anti-typhoid inoculation in the South frican War and in opsonic investigations of the staphylo- occus and brucella melitensis."

another page Sir Harold Scott refers to "Sir Almroth ght's anti-typhoid vaccine."

t is to be noted that Wright's anti-typhoid work an in the summer of 1896 (see *Lancet* of Sept. 19, 6, p. 807); whereas, according to Sir Harold Scott's ement, Leishman was posted to Netley in 1897 as lical officer. It is also noteworthy that Leishman's ıe appears as joint author of only one of the series five important papers on anti-typhoid inoculation lished by Wright between 1897 and 1901, the one earing on Jan. 20, 1900, in the *British Medical rnal*—that is, 3½ years after the beginning of the work. o check my memory (not at first hand) of these nts, I recently wrote to one who was a pupil of ght's at Netley and himself took part in the early k on anti-typhoid inoculation. He replied that, in view, "Wright and Wright alone was the originator nti-typhoid inoculation with killed vaccine"; and ıdds that Leishman was not even on the laboratory f at that time. "He had nothing to do with the oduction of anti-typhoid vaccine."

It would seem, then, that Dr. Guthrie has in some way been misinformed on this matter. I hope that, in honour of the greatest figure in English bacteriology, this mistaken attribution of credit may be put right before it gets copied into other books.

Birmingham Accident Hospital.   LEONARD COLEBROOK.

MYTH AND MUMPSIMUS

SIR,—The author of your opening article of August 31 must surely be a young man who delights in pulling the legs of the elderly, but even the presbyopic must see that he is erecting Aunt Sallies for the simple pleasure of knocking them down. On the high spirits and harmless games of youth it would be ungracious to frown, but some of his statements require modification.

1. Dr. Forbes lumps together phlebotomy and exorcism and consigns them both to Limbo. But exorcism was surely always a priestly performance, and phlebotomy properly practised is as useful today as it was in the years before its very success led to its disastrous excess.
2. He appears to approve of increasing the fluid intake if large doses of sulphonamides are given, but he scorns any other reason for promoting diuresis. Are there no other drugs whose concentrated presence may damage the kidneys?
3. He scoffs at diaphoresis and hot baths, but has he never known their benison after a long day in the saddle? Is there no physiological explanation for tired and stiff muscles and have we not in steam a proper therapy?
4. The next time he has to cope with an outbreak of gastro-enteritis, I will wager my old Culpeper to his new Martindale that he will achieve far quicker healing if he will give his patients an ounce of castor oil before he starts them on sulphaguanidine. He writes: "*horribile dictu.*" I reply: "*experto crede.*"
5. Dr. Forbes's fundamental conclusions about enemata and his rejection of all solutions except normal saline may appeal to the youth who has never known the agony of rectal ballooning, but these conclusions will annoy the clinician who has seen what relief a turpentine enema can produce when all the normal saline in the ward has failed to charm forth any scybalæ. He states that "the complete efficacy of normal saline was proved long ago." By whom and where and when?
6. Dr. Forbes then pens the following sentence: "The adolescent girl who is pale, who will not eat, and who faints easily is in all probability working *too hard* at school and pining with unrequited love for her form mistress." This he calls a psychological upset. Has he never seen a case of chlorosis?
7. He says, "leeching and blistering which survived and were universally practised for centuries and yet have now been totally discarded." Have they? If "'tis true 'tis pity," or so it would seem to those of us who have watched the painful pericarditis or pleurisy relieved by leeches.

I am no *laudator temporis acti* but I wish to protest emphatically against throwing away the baby with the bath water.

London, W.1.   CHRISTOPHER HOWARD.

SIR,—In his delightful paper Dr. Forbes makes an earnest plea for definition of terms, with which many of us must be in full sympathy. To show my appreciation in a practical manner, I should like to set the ball rolling towards elucidation of the (now fashionable) term "psychosomatic." Others can then kick it about and eventually it may reach its goal. Meanwhile a good time will be had by all.

It is easier to give a concept of this term than actually to pin it down by a *definition*. My own tentative conception is that it is analogous to the term "electro-magnetic." In an electromagnetic system it is impossible to alter the flow of electricity without altering the magnetic field. Conversely any variation in the magnetic field is at once reflected in the electrical potential. The two are as inseparable as the heads and tails on a coin, being merely different observable aspects of the same phenomenon. In the same way every alteration in the psyche affects the soma, and vice versa, because (and this is the important and difficult point to grasp) they are different but interdependent aspects of the same phenomenon—a living individual. There is no question of mind over matter or matter over mind. Mind and body, psyche and soma, are as inseparable as inside and outside.

It would therefore appear meaningless to refer to "psychosomatic disorders" as though they were certain recognisable diseases in a class of their own, distinct from other diseases. The phrase "psychosomatic medicine" does, however, suggest to me a certain approach to disease and health. It suggests investigating the patient as a whole, accepting the idea that in every condition of life both psyche and soma are affected, and (in practice) treating whichever is handier.

There is nothing new in this. General practitioners have been doing it for centuries. But with the advent of every new specific drug, serum, vaccine, and operation, the emphasis is shifting more and more towards soma and farther from psyche. General medicine (and surgery in particular) is concerning itself increasingly with ridding a patient of the physical handicap of his illness and getting him back to work. Sometimes this is rather like performing highly skilled running repairs on the car, when really it may be the driver who needs attention. Psychosomatic medicine, studying the patient as a whole, would seek to make it unnecessary for him to break down.

Such is my conception, and I am only too eager to revise it if it be found wide of the mark by my betters.

Mundesley. GEORGE DAY.

SIR,—May I congratulate Dr. J. R. Forbes on his paper of August 31? With the possible exception of those relating to fluid-intake, I feel each one of his remarks is most sane and timely. Of paramount importance are his references to the medically induced neurosis. The abysmal ignorance, exhibited by general practitioners and general consultants alike, concerning the ætiology, prevention, and treatment (usually so simple and straightforward) of the common neuroses is one of the most depressing and deplorable aspects of modern medicine. This lack of simple knowledge, fostered and perpetuated as it is by a mental attitude of derision, means that, for every patient cured by the exhibition of one of medicine's modern therapeutic triumphs, at least one (probably more nearly half a dozen) is allowed to sink irretrievably into chronic invalidism and the misery of a life of medically induced or medically perpetuated neurosis.

Port Talbot. R. J. T. WOODLAND.

SIR,—Dr. Forbes has handled a very awkward subject and presented it in a most acceptable and entertaining manner. It has long been my ambition to write a paper on the same subject.

During nine years in charge of the diphtheria wards of a fever hospital I could never convince any of the sisters that lying flat on a hard mattress without a pillow was most uncomfortable, and therefore not restful. I was looked on with horror and told that every school of nursing insisted on cases of diphtheria being kept flat without a pillow for at least three weeks. They simply would not accept the fact that the same absolute rest could be attained more effectively if the patient had a pillow for his head instead of rolling it from side to side on a hard mattress. Yet all the sisters slept with a pillow or two under their heads.

Manchester. J. EGAN.

PENICILLIN BY INHALATION

SIR,—The papers by Dr. Humphrey and Dr. Joules (p. 221), and Dr. Southwell (p. 225) in your issue of August 17, tempt me to record my own short series of observations.

I used a Collison's inhaler and gave five minutes' inhalation every hour from 6 A.M. to 10 P.M. of a solution of penicillin containing 5000 units to the c.cm. Three cases of postoperative bronchopneumonia and 4 of postoperative bronchitis responded most satisfactorily. The bronchopneumonia cases presented dullness and impaired breath sounds with radiological opacities, but had not progressed to the stage of bronchial breathing and bronchophony. A case of postoperative confluent *Staphylococcus aureus* pneumonia did not respond at all, though relieved promptly by parenteral penicillin. I have not cared to try this form of therapy in any other lobar or confluent bronchopneumonia. Four of chronic bronchitis and a comparatively mild bronchiectasis improved in that the sputum from mucopurulent to mucoid and lessened in am though an appreciable quantity remained. A ca postinfluenzal bronchitis and one of a low-grade influenzal bronchopneumonia with mucopurulent sp. believed due to secondary bacterial infection respo promptly and completely; the latter had *not* respo to parenteral penicillin. On the other hand, 2 cas atypical pneumonia considered of virus origin, with serum cold-agglutination titres and plentiful purulent sputum, improved hardly at all. I interested in Humphrey and Joules' observation *Bact. coli* appeared during treatment, as the same occurred in several of my cases.

I have formed the impression that penicillin inhal has a definite rôle to play in the treatment of acce bacterial infection with organisms susceptible to p cillin, with or without underlying pathological condit Underlying conditions such as chronic bronch bronchiectasis, or a still active virus disease re unaffected. I suspect that consolidated lung is inacc sible to penicillin by inhalation.

I am indebted to Air Vice-Marshal A. F. Rook, con in medicine to the R.A.F.M.S., for encouragement assistance in this investigation.

Ely. D. FERRIMAN.

SUPRAPUBIC PROSTATECTOMY

SIR,—In suprapubic prostatectomy with closure, commonly performed, a catheter is passed from t external meatus, through the urethra, into the bladd and then fixed in place. It is a common experi that it often tends to stick in the cavity which has been occupied by the enucleated "prostate." Even india-rubber coudé catheter may so stick. During t last couple of weeks, by borrowing a tip from M McGill, we seem to have overcome this difficulty. McGill's intratracheal tubes were originally made himself from ordinary tubing and given their requ curve by storing the tubes in round tins. We underst they are still so stored. By sterilising catheters, kno as whistle-tipped in England and as McCarthy ela tomes in America, in 2-oz. tobacco tins and leaving th in the tins for a couple of days they acquire a cu which seems to permit them to ride smoothly into t bladder. The 2-oz. tobacco tin can accommodate th 22F catheters.

This procedure is so simple that it is unlikely to original, but it has proved so useful that this note help those who have not heard of it.

Dublin. T. J. D. LANE

FUNICULITIS

SIR,—With reference to Lieut.-Colonel Power's inter ing paper on funiculitis in British troops in Cey (April 20), may I draw his attention to a paper by m published in THE LANCET many years ago (August, 1 on the disease I called "endemic funiculitis"? A fu complete description of it with four illustrations m found in Castellani and Chalmers *Manual of Tr Medicine* (3rd ed., p. 1939), in which, in addition t acute type, mention is made of a mild form with thr bosis of the veins, without suppuration. To this la type, I feel, belong Lieut.-Colonel Power's cases.

What is the ætiology of endemic funiculitis? In my Ceylon cases I found a virulent streptococcus; some of them there was also a filarial infection. I believe that the streptococcus plays by far the important ætiological rôle, and that the condition arise also when there is no concomitant filarial infecti At any rate even if the syndrome should be consid of filarial origin, it is clinically so characteristic that deserves being given a full description and not dismis in a few words, as is done in so many books on trop medicine. It must be kept in mind that the acute is a very serious disease and is of great practi importance, since often, if the correct diagnosis is made in time and the appropriate treatment not gi immediately, a general streptococcal infection devel with grave risk to the patient's life.

Sintra, Portugal.

ILDREN WHO SPEND TOO LONG IN BED

r,—Dr. McCluskie's stimulating article of August 31 welcome addition to the growing body of common- advice about infant and child care. Hardly a e criticism he has made could not be illustrated from y cases known to any G.P. Most illustrative, aps. of a typically "successful" parental domination ie child of 3 that "lay from 6 A.M. until 8 A.M. wet bed playing with the blankets." It is this rmination to "train" the unfortunate babe, from moment of its arrival, for the convenience of its nts' pre-existing habits that has such lamentable hological results. Instead of making an attempt ompromise, the parents endeavour (fortunately often out success) to mould the child hourly into their own t groove.

hus, many modern maternity nurses teach mothers eave their baby to cry, whatever their maternal incts. between the rigidly set feeding times: how h this tends to destroy the rapport between mother child is clear to see. I have known mothers to sit nised, in obedience to this teaching, watching the k creep round from 5.15 to 5.30, 5.45, before guiltily ing up the baby ten minutes early for its 6 o'clock , for a little overdue mother-love.

ne could cite such things ad nauseam—the rigidly sured feeds. to be taken each time. never an ounce e left, nor an ounce extra given: the agony of the kly weight figures if there is a week's stasis: the iety if an 18-monther soils his trousers. In brief. the lern mother is invited to consider her baby as nothing e than a machine, requiring mathematical precision reatment and nothing else.

great deal of the fashionable "training" seems to essentially at ensuring the minimal disturbance of t domestic routine which existed before the arrival he first child. without due regard for the child itself. o main themes of our instruction to mothers should ely be these: (1) A frank admission that parenthood ans unselfishness and "giving out." especially of e and individual understanding; at the least striking air balance between needs of parent and child. and her erring on the side of "putting the children first" unfashionable phrase today) than dominating them parental convenience. (2) While setting out the essary feeding time-table, principles of child care and nagement, &c.. we should insist that the mother ognises that they are *only for guidance*. and not to slavishly adhered to like a railway time-table or legal le. Child psychologists would find their work lightened the parents could be educated to ignore the "baby a machine" school of management, and to rely on eir own instincts and judgment in solving individual blems.

reenhithe, Kent. G. F. TRIPP.

SIR,—My article—which incidentally is quite unworthy the publicity it has received—does not describe a ime-table" for infants and toddlers but a "plan" on ich to base a time-table. It states quite plainly that each child as he develops will soon give his mother an lication of how much day-sleep he requires" if the an is followed. Rigid time-tables create an obsessive nd in both the mother and the child. and too much phasis cannot be laid on the part played by mother- e in the successful handling of a child.

The individual variation suggested by me is not 30 nutes but an hour, or more. or less. (Approximately minutes is the time named. but some mothers may d it necessary to add; others to subtract.) Neverthe- s. having regard to Professor Bühler's table of actual servations, which were timed not to the nearest half- ur but to the nearest second. this variation may be large. I understand some American physicians are rrying out stop-watch nursery recordings and I await eir results with interest.

Between the fifth and the tenth months an infant o sleeps too long in the mornings becomes cross in the ernoons because he cannot sleep. It is easy for a other to prevent an infant sleeping too long in the orning and so gain the benefit of the afternoon rest d no crossness.

From years of experience with children I find that the lthy child of three years at home begins to prefer all his sleep in one dose. But there is no harm in routine day-sleep above this age provided always (*a*) the length of the day-sleep is related to and not in competition with the night-sleep, and (*b*) that it is the child's physiology and not the teacher's boredom that calls for it. Where there are two or more children who can play outside, day-sleeps can be tiring and exhausting for the mother. because they involve undressing. re-dressing. and remaking of beds. (The practice of putting children to bed during the day with their clothes on is a bad one because it causes overheating of the skin and sometimes sweating.)

"Rounds of pottings," indeed! I have 3 children under six years who have never had a routine "round of potting" in their lives because they go to bed to sleep, not to be taught bad habits.

There is too little respect for genuine motherhood in Britain and too much kow-towing to a nation-strangling matriarchy.

Westcliff-on-Sea. JOHN A. MCCLUSKIE.

FAVUS IN DEVON

SIR,—Whether it be due to an influx from elsewhere or to an indigenous source of infection, there is some evidence of an outbreak of favus in North Devon. Scutula are not always easy to find, nor are the nails often affected, but with Wood's glass, a hand lens, and a microscope the infected hairs on the scalp, tiny crusts surrounding hairs, and incipient bald patches can be noted. Ringed lesions. from which the crusts have been removed by treatment, have led to the diagnosis of "ringworm" of the glabrous skin.

Exeter. H. W. ALLEN.

EFFECT OF PHOSPHATE ON CARBOHYDRATE ABSORPTION IN SPRUE

SIR,—In our preliminary communication (*Lancet*, 1945, ii. 635) we reported experimental evidence that in active sprue there may be "a failure of the phosphorylation of glucose at the time of its absorption." It was our intention to continue our researches and publish the results in detail later, but unfortunately (or fortunately?) the cases suitable for experiment have been too few to provide anything more than indications of the direction in which future research should be developed. For the benefit of others who are more favourably placed for doing experimental work, it seems worth while recording our results of the effects of adding phosphate to carbohydrate solutions administered to cases of active sprue.

In our first experiment a case of active sprue with characteristic history of loss of weight, flatulent dyspepsia, and glossitis was selected and placed on a simple milk diet. An oral sucrose-tolerance test was carried out and the usual flat glucose and normal fructose absorption curves obtained. To confirm that the flat glucose curve did not arise from hold up of the sugar in the stomach, the test was repeated, the sugar solution being injected by tube direct into the duodenum. The resulting glucose-absorption curve was again flat and the fructose normal. Glucose was next injected intravenously, and. as Fairley has found in other cases of sprue, the curve of disappearance of the sugar from the blood was within normal limits.

It was clear that in this case the flat glucose curve was due neither to delayed stomach emptying nor to rapid removal of the sugar from the blood. and was therefore presumably due to failure of absorption. We decided to investigate this failure of absorption by studying the points at which the complicated process of phosphorylation might fail. The accessibility of the phosphate ion was investigated first. We argued that if the phosphate were unavailable because it was absent (which was unlikely on a milk diet) or because it was present in some inaccessible form, then phosphorylation should be restored by the exhibition of the phosphate ion. We therefore repeated the sucrose-tolerance test, administering the sugar (100 g.) direct into the duodenum and adding to it 8 g. of a mixture of potassium acid phosphate and disodium phosphate buffered at pH 7·0. The result was startling. The glucose curve was now normal. the fructose curve remaining unchanged. A week later the sucrose test was repeated without phosphate and the resulting glucose curve was again characteristically flat, the fructose remaining normal. Some time later the sucrose test plus phosphate was repeated by mouth and again a normal glucose curve was obtained. The relevant figures obtained in these experiments are given below:

DUODENAL ADMINISTRATION OF SUCROSE (100 G.)

Time (hr.)	Dec. 12, 1945 (no phosphate) Glucose	Dec. 12, 1945 (no phosphate) Fructose	Dec. 19, 1945 (8 g. phosphate mixture) Glucose	Dec. 19, 1945 (8 g. phosphate mixture) Fructose
	mg. per 100 c.cm.		mg. per 100 c.cm.	
0	90	0	60	0
$^1/_2$	70	15·3	153	7·0
1	76	15·7	114	10·0
$1^1/_2$	70	10·3	55	7·9
2	82	8·4	51	7·0
$2^1/_2$	80	6·0	62	5·2

We have repeated these experiments in a modified way on 3 other cases of sprue, none of which was, however, in a very active stage of the disease. In 2 of these cases the phosphate appeared to assist the absorption of glucose; in 1 it had no effect.

These results are offered in letter form because they are so incomplete and because we are unable to go on with the work owing to lack of cases. I think the results show that in some cases of sprue at any rate the failure of absorption of glucose is connected with failure of phosphorylation of the hexose arising from an apparent inaccessibility of the phosphate ion. In other cases the complicated mechanism of phosphorylation may have broken down elsewhere.

In cases in which the absorption of glucose is restored to normal in the presence of the phosphate ion, the latter might prove a valuable therapeutic agent.

School of Tropical Medicine, University of Liverpool. BRIAN MAEGRAITH.

PERSISTENT ENURESIS

SIR,—Neither Stalker and Band's paper[1] nor your annotation on it (August 17, p. 243) mentions the possibility of endocrine treatment of enuresis, although evidence is available that points to a definite influence of the sex hormones on the urinary system and also, to some extent, on disorders of micturition.

The close developmental and anatomical connexion between the genital and the urinary system provides a basis for understanding a possible action of the sex hormones on the urinary tract. Œstrogens in large doses have occasionally produced bladder distension and hydronephrosis in male and female mice.[2] There is reason to assume that the ureteral dilatation which frequently occurs in women during early pregnancy is due to œstrogenic action and not to mechanical obstruction, for which no evidence exists. Urinary symptoms, such as frequency, urgency, and incontinence, are often encountered in menopausal women and respond remarkably well to œstrogen treatment.[3]

Androgens produce hypertrophy of the urethra in males and females and possess nephrotrophic properties; testosterone produces a true parenchymatous hypertrophy, principally of the cells of the renal tubules. This hormone has also been shown to increase the tonus of the bladder. *Intravesical pressure after introduction of* increasing amounts of fluid is higher after treatment; the maximal pressure which can be tolerated without pain and the pressure at which desire to urinate is experienced are increased.[4] Everybody who has used androgens in the treatment of prostatism knows that, though it is without influence on prostatic enlargement, the distressing symptoms associated with micturition improve. The size of the urinary stream increases, and the tonus of the detrusor and probably of the sphincter muscles is augmented (cf. Egger[5]). Greenblatt[6] treated 34 women suffering from nocturia, frequency, and incontinence with testosterone parenterally, by mouth, and by pellet implantation. His results were good, in cases with fibroids where orthodox teaching t attribute nocturia to mechanical pressure. St Band have stressed the point that nocturnal and d frequency, urgency, and sometimes diurnal enuresis be associated with enuresis nocturna.

Enuresis in children has been treated by Hoff with urinary gonadotrophins, and he claimed suc Testosterone propionate was used by Zehn,[8] who in 5 mg. for a short period daily, then every third or f day, and claimed excellent results. Schlutz and A son[9] treated 50 children, 36 boys and 14 girls, bet the ages of $3^1/_2$ and 14 years with daily injections 25 mg.), inunction, or oral application of male hor 54% were cured, 34% much improved, 12% rem unaffected within 2 months. The authors think failures were partly due to irregular medication. In cases the effect was dramatic but one case required ment for a year. No undesirable effects were prod relapses occurred but resumption of treatment w followed by response. Treatment was combined fluid restriction, high salt intake, and getting the up once in the early part of the night. Most cases on this management for some time but did not impr before hormone treatment was instituted.

I have treated a small number of cases with testosterone in doses of 5–10 mg. per day, some comb with inunction of testosterone ointment on the part of the abdomen. The number is too small to all conclusions but all seemed to respond. One boy 14 years has been symptom-free for the last 9 mont In all cases treatment had to be continued for sev months; larger doses or parenteral application mi have produced results in a shorter time. No untow side-effects were encountered. It may be mentioned th two of the children had radiological abnormalities the first sacral vertebra.

Without underrating the complexity of the pr of enuresis, I believe that androgen treatment is enough to be tried on a larger scale, and that, on t strength of the published data and my own observat results may be expected in a certain proportion of c To establish the value of this therapy definitely an eliminate psychological factors which may easily in the response to any treatment in enuresis, control c will be needed who are treated with an inert subst

London, W.1. H. Uc

SUPPLEMENTARY FOOD FOR PREMATURE INFANTS

SIR,—Many will have read with interest the ar by Jorpes, Magnusson, and Wretlind (August 17), s forth the results they obtained by giving pr infants breast milk supplemented with casein hy lysate and glucose. I hope the writers will give us further details. For example, did the control ba who had breast milk only receive the same total ca intake as the "treated" infants, or was the amo glucose given as an extra? Have they evidence the effect of giving hydrolysate on neonatal mort or on the development of infants by, say, 6 mo of age?

If I am correct in understanding that the amino glucose was an extra, it would seem that the contro on breast milk alone, received at first "minimal requirements for life," and later an average of calories per kg. (45 calories per lb.), daily, whereas infants with the supplement received over and ab this allowance nearly 20 calories per kg. extra. If t were so, might not the improved gains of babies recei the hydrolysate be due simply to their improved ca intake? Since a casein supplement might be po tolerated by a premature infant, the deficient incre in weight in the group given casein would not dispr this suggestion. The increases in weight of Pro Magnusson's controls, on breast milk alone, are le than those I am in the habit of seeing among premat infants born and supervised in a maternity hosp and given a more liberal calorie intake (*Arch. Dis. Chi* 1941, 16, 166). These babies are fed on breast mil

possible, supplemented as necessary, when this
hort, with half-cream dried milk and sugar, or with
nsed milk. They usually gain weight at a rate
ferior to their full-term fellows—i.e., about 5–7 oz.
y or 25 g. daily after the first week of life, which was
ximately the rate of gain of the babies given
sol. There are undoubtedly wide differences of
n as to the level of calorie intake conducing to
owest mortality-rates among young premature
s, but there is no doubt that gains are likely to be
vely small if the daily calorie intake is kept as low
calories per lb. body-weight.

e Swedish workers comment that doses of hydro-
e larger than those they advocate often caused
ting or regurgitation of food—and I too have
ntered difficulties when giving casein hydrolysate—
at it behoves those who try this supplement to use
h caution. If it should turn out that the important
of the hydrolysate supplement was that it provided
calories, then an increase in the breast-milk
ance may still prove preferable. Perhaps Professor
usson can clear up some of these points and correct
I have misunderstood.

A SYNDROME SIMULATING ACUTE ABDOMINAL DISEASE

,—When I read the interesting description of their
rome by Mr. Goldstone and Dr. Le Marquand
ust 24) I was puzzled by the omission of Bornholm
se from the differential diagnosis. Neither does
ram mention it in his letter of Sept. 7.

attention was first drawn to this disease some years
by Dr. W. N. Pickles but I saw no examples of it
I was posted to Naples last May. Reference to these
nts has been made in your columns by Reynell
ect, 1946, i, 977) following Scadding's description of
s in the Middle East (*Ibid*, p. 763). Meyer also wrote
t cases in C.M.F. (*Ibid*, p. 902), while Martindale
ribed an outbreak on a frigate in the Indian ocean
l, p. 834).

oldstone and Le Marquand ask three questions:
"Why does it develop on the right side only?"
lemic diaphragmatic myalgia occurs on either side,
the authors discuss the condition in reference to the
ute abdomen," and, as Scadding points out, abdo-
al signs are predominantly right-sided. The pain
ally is often central or bilateral, but abdominal
lerness is usually only found under the right costal
gin. Pressure there may produce in addition pain
e shoulder or neck. Presumably the upward pressure
he liver is transmitted to the diaphragm. Further-
e, on seeing a patient with pain on the left side, one's
ntion does not immediately descend to the appendix
gall-bladder, as it naturally does when pain is on the
t. The picture with involvement of the left side
e resembles that of acute dry pleurisy, and does not
eadily attract surgical attention.

"Why does it develop so often in West Africa,
rarely in U.K.?" This is an epidemic condition.
may wait for years without seeing it, in the U.K.,
taly, or in W. Africa, and then suddenly it is common.

"Might the syndrome be due to an unusual type
epidemic?" Speaking from the armchair, my
er is "yes."

he authors suggest that the cause may be perinephric
hylococcal infection. Four of the thirteen patients
had boils. Is this surprising in European Servicemen
. Africa? Four had preliminary periods of malaise.
his unusual in patients admitted with other acute
sses? One of the authors' patients developed a right
nephric abscess. One of mine had a right apical
erculous cavity but this does not make the rest
erculous.

r. Oram suggests that latent or subclinical infective
atitis may possibly produce such symptoms. I do
think so, for I saw a lot of infective hepatitis in Africa
Italy from 1942 to 1946, but did not see patients with
e devil's grip" until this year. There was none in
n while I was there; a few days later I saw examples
aples; yet infective hepatitis was common in both
es.

ckfield, Sussex. PHILIP EVANS.

NUTRITIONAL OPTIC NEUROPATHY

SIR,—The article by Dr. Fitzgerald Moore in your issue of August 17 is of such interest to me that I would like to make some observations on it.

The first real recognition of the syndrome of epithelial and nervous lesions complicated by nutritional optic neuropathy was by H. Strachan,[1] in 1897; I referred to his work in my privately printed paper[2] which Moore mentions.

Strachan in 1888 drew attention to a form of multiple neuritis prevalent in the West Indies. By 1897 he was convinced he was seeing an unrecorded form of neuritis, and stated that its chief features were: "(1) A more or less widespread neuritis, involving some of the nerves of special sense, especially the optic nerve. (2) The occurrence of trophic changes in the skin along the distribution of the nerve terminations, in the muscles, in the mucocutaneous lines, and occasionally in the cornea. (3) The rare but still to be noted occurrence of monoplegias. (4) The fact that the disease may be very severe, lasting for many months or even years. (5) The fact that recovery is the rule and a fatal termination very rare. (6) That it attacks many hundreds of persons, at least in Jamaica, the great majority of these being black or coloured inhabitants, who constitute the bulk of the population, though the white residents are not exempt by any means."

Strachan next detailed some of the most important signs and symptoms and described paræsthesias and gradually increasing impairment of vision, but noted that recovery of sight was the rule and optic atrophy never resulted. He also referred to "the condition of the mucocutaneous orifices" and said: "This demands some little notice as redness and irritation of the eyelids and lips are often the first signs noticed. It soon passes into a slight eczematous condition, especially at the corners of the mouth and round the margin of the nostrils, with fine branny desquamation. A similar condition in the mucocutaneous line in the prepuce is not uncommon. More rarely there is a similar condition of vulva and anus. The lips and inside of the mouth are hyperæmic and there may be much loss of surface epithelium on the tongue."

It is of great interest that Strachan recorded pigmentation of the palms of the hands and soles of the feet. Sensation was blunted and in grave cases involvement of the innervation of the heart and diaphragm led to death. He saw mental involvement only in two or three cases but said such cases could be found in asylums. There is little doubt that he was seeing cases of beriberi and pellagra as well as the syndrome under discussion, but his treatment was nevertheless correct, and consisted in rest in bed and nourishing food gradually increasing in quantity and variety throughout the early and acute stages. Medicinal treatment was given for the malaria believed to be present, and iodides to promote absorption of the inflammatory material in the affected nerves.

Moore says the condition I described in 1928[3] was identical with that described by Stannus. This is not so. I found defective vision a cause of constant complaint, whereas Stannus[4] records finding only 5 patients with defective vision out of a total of 131, which means there is no conclusive evidence of defective vision in his report. Moore still makes it appear that I first attributed the Sierra Leone disease to avitaminosis in 1930; but it was in 1927 that I attributed it to A and B deficiency[5] and it was then that I introduced the "active treatment" with yeast and cod-liver oil.

Recently Hobbs and Forbes[6] referred to the prophylactic value of first-class protein in nutritional visual defects, and it is interesting to recall that Clark,[7] who investigated the syndrome of epithelial and nervous lesions in Nigeria, concluded that cyanogenic foodstuffs,

Medical Women's Federation

The London Association of the federation is to hold an evening reception for the council and delegates of the Medical Women's International Association, which is meeting in London this month; the reception will be held at the London School of Medicine for Women, 8, Hunter Street, W.C.1, on Thursday, Sept. 19, from 8 to 10 P.M. The London Association's annual general meeting will be held at B.M.A. House, Tavistock Square, W.C.1, on Tuesday, Sept. 24, at 8.30 P.M.; Dr. Henriette A. Lohr (Amsterdam) will speak on Medicine in Holland under German Occupation.

Lectures on Child Development

The Provisional National Council for Mental Health is holding ten weekly lectures on this subject, beginning on Wednesday, Oct. 9. The lectures are intended for school medical officers; the first will be given by Dr. Kenneth Soddy, director of the council, and the others by Miss R. Thomas, educational psychologist. They will be held at 39, Queen Anne Street, London, W.1, and further particulars may be had from the educational secretary of the council at that address.

Iraq Appointment

Lieut.-Colonel W. R. M. Drew has been appointed professor of medicine at the Royal College of Medicine, Bagdad, in succession to Sir Harry Sinderson.

Lieut.-Colonel Drew, who is 38 years of age, graduated B.SC. at Sydney in 1929 and M.B. in 1930. He joined the R.A.M.C. in 1931, and served in India from 1932 to 1937, except for a period as house-physician at the British Postgraduate Medical School in 1935. In 1938 he became a M.R.C.P., and in 1939 obtained the D.T.M. & H. He returned to the Postgraduate Medical School as clinical tutor, but on the outbreak of war joined the B.E.F., being awarded the O.B.E. after the evacuation from Dunkirk. Since 1942 he has been *responsible for the teaching of tropical medicine at the Royal Army* Medical College, Millbank, and for the last two years he has been joint hon. secretary (with Dr. N. Hamilton Fairley, F.R.S.) of the Royal Society of Tropical Medicine and Hygiene. He was elected F.R.C.P. in 1945. His published work includes studies of primary atypical pneumonia, the toxicity of mepacrine, and sprue.

Royal Sanitary Institute

Dr. F. T. H. Wood, medical officer of health for Bootle, has been elected chairman of the council of the institute.

Births, Marriages, and Deaths

BIRTHS

AHERN.—On August 5, at Graz, Austria, the wife of Colonel T. M. Ahern, O.B.E., R.A.M.C.—a daughter.

BARNSLEY.—On Sept. 1, at Shorncliffe, Kent, the wife of Dr. Alan Barnsley—a son.

CHILD.—On Sept. 5, at Oxford, the wife of Dr. J. P. Child—a son.

DOVE.—On Sept. 3, at Liverpool, the wife of Dr. W. L. Dove—a son.

FLACK.—On Sept. 5, the wife of Dr. I. Harvey Flack—a son.

GOULSTON.—On Sept. 3, in London, the wife of Dr. S. J. M. Goulston, M.C., M.R.C.P., of Sydney—a daughter.

HAYWARD.—On August 31, at Cardiff, the wife of Dr. J. J. Hayward—a daughter.

LEITH.—On Sept. 1, the wife of Dr. W. F. Leith—a daughter.

MACLURE.—On Sept. 4, at Kamakwie, Sierra Leone, the wife of Dr. H. L. Maclure—a son.

NORMAN.—On Sept. 4, at Llandrindod Wells, the wife of Lieutenant Thomas Norman, R.A.M.C.—a son.

PARSONS-SMITH.—On August 31, at Caterham, the wife of Dr. Gerald Parsons-Smith—a son.

PICKARD.—On August 31, the wife of Dr. H. M. Pickard, of Endeleigh Court, London, W.C.1—a daughter.

SAUNDERS.—On August 30, at Barnstaple, the wife of Mr. K. G. W. Saunders, O.B.E., F.R.C.S.E.—a son.

SCOTT.—On Sept. 2, at Malvern, the wife of Dr. G. S. Scott—a son.

STANLEY.—On Sept. 5, at Portsmouth, the wife of Mr. B. E. C. Stanley, F.R.C.S.—a daughter.

WATSON.—On Sept. 5, the wife of Dr. G. I. Watson, of Vachery Shere—a son.

MARRIAGES

BRAINES—STONE.—On August 26, in Guernsey, Frederick Morley Braines, M.B. Lond., to Beryl Winifred Stone.

HODGKIN—CANDLER.—On Sept. 4, at Clyst St. George, Devon, George Keith Hodgkin, B.M., to Rosemary Candler.

MACALEVEY—ALLPORT.—On July 20, at Singapore, Gerald Esmond MacAlevey, C.B.E., D.S.O., M.C., *brigadier* R.A.M.C., *to* Hilda Mary Allport, Q.A.I.M.N.S.R.

TAYLOR—LYNE.—On Sept. 6, in London, John Henry Taylor, M.R.C.S., to Joyce Winefred Lyne.

TOW—CARROTT.—On Sept. 5, Peter Macdonald Tow, M.B., of Wickford, Essex, to Evelyn Mary Carrott.

WILSON—IVOR EVANS.—On Sept. 4, at Swansea, Peter Remington Wilson, M.R.C.S., to Joan Ivor Evans.

DEATHS

BENNETT.—On Sept. 2, in Manchester, Christopher Henry Wentworth Bennett, M.R.C.S., of Sandbach.

BETTS.—On Sept. 1, at Kingsdown, Deal, Alfred John Vernon Betts, M.B. Lond., *lieut.-colonel* I.M.S., aged 72.

MACPHERSON.—On Sept. 5, at Oxford, Alexander Hill Macpherson, L.R.C.P.E.

: routine prophylactic use, in severe battle
lties, of intramuscular doses of penicillin prompted
vestigation into the penicillin content of wound
tes after 100,000 units, the recommended initial
It was hoped to determine whether such a dose
l be followed by exudation of the drug into a wound,
vhether it would remain longer there than in the
-stream, thus exercising a protective effect during
periods in transit, in which no injections were
. When this time-limit was found, the same
vas placed locally in the wounds, and the duration
rotective concentration in blood and wound exudate
ing each method of administration was compared.

METHODS

udates were first collected from 22 lacerated wounds
rborne battle casualties at the first removal of
ngs in the Radcliffe Penicillin Unit, and at different
rals following the immediate administration of
00 units of penicillin.

ing to circumstances over which the Unit had no
ol, the supply of fresh cases ceased after three
hs, and so, as the experiments continued and the
wounds had to be used, the age of the latter
ased until the last one was 67 days old. The
diate effects of trauma, therefore, could only have
ed an influence on the earlier results. Intramuscular
nistration was investigated before local when
itions more nearly approached those for which this
od of prophylaxis had in fact been used.

llection was usually by means of a Pasteur pipette,
a rubber drainage-tube was used on one occasion
glass tube on five occasions. When collection took
than a few minutes, the collecting vessel was
unded with ice.

says of blood and urine were also carried out to
tain if there was any correlation between penicillin
entration in the three fluids.

e method of assay used for low concentrations either
e blood-stream or wound exudate was Heatley's
-on-slide method (Garrod and Heatley 1944). For
and wound exudate, when enough was collected
when the presence of more than 0·1 unit per c.cm.
l be expected, the cylinder-plate method (Heatley
) was used. To make the test more delicate, the
s were seeded with a 1 : 1000 dilution of broth culture
e test staphylococcus (N.C.T.C. no. 6571).

ntrols were obtained for wound-exudate samples
e addition of penicillinase or by using those collected
ng after the last administration that they were free
nicillin.

fficulties in Interpretation.—The reading of slide
was made difficult in centrifuged exudates by the
ent presence of contaminating bacteria. To exclude
readings from inhibition of the test staphylococcus
e contaminants, a series of tests was set up in which
n was inoculated with the test staphylococcus and
one of six varieties of gram-negative bacteria
red from the wounds. Various dilutions of
nsions of the contaminants were used for inocula-
Though they prevented the typical appearance of discrete colonies, microscopical examination always revealed a free though more diffuse growth of staphylococci in the presence of *Ps. pyocyanea* and *Bact. coli*. In the presence of proteus, growth though less abundant took place in every concentration used.

The greatest problem to be overcome, however, was the presence of some inhibitory factor, or factors, other than penicillin in the exudate. Nine wound exudates inhibited the test staphylococcus even when incubated with penicillinase; so their assays are excluded from the tables. Considerable efforts were made to eliminate this factor and to find its source. It was not produced by the gram-negative bacteria infesting nearly all the wounds, nor was it associated with rubber tubing or its preservative. Moreover, it appeared in a sterile serous exudate after it had been incubated for three hours.

Extraction.—Eventually a method of extraction was developed which ensured that penicillin alone was assayed. It depended on the use of ammonium sulphate, of high pH, to precipitate the globulins, and of amyl acetate and phosphate buffer for the actual extraction. To reduce penicillin loss, samples were kept, from the time of collection till the final extraction, in a beaker containing ice, only being removed when centrifuged or shaken. The method was as follows:

(1) The samples were centrifuged until a comparatively clear supernatant fluid appeared.
(2) This was removed with a pipette and diluted if necessary with saline, to make a minimum of 0·4 c.cm.
(3) Ammonium sulphate, equal by weight in grammes to half the volume in c.cm. of the sample from (2), was added and the mixture well shaken.
(4) It was centrifuged at 4500 rev. per min. for about 20 min.—i.e., until there was a sufficiency of clear supernatant fluid to use in the next steps.
(5) A volume of amyl acetate equal to that of an aliquot of the supernatant fluid was added.
(6) During gradual acidification to pH 2·0 with N/3 HCl † persistent shaking was carried out to prevent destruction by the acid before extraction had taken place.
(7) The supernatant amyl acetate was separated and removed.
(8) An equal volume of M/15 sterile phosphate buffer at pH 7 was added to the amyl acetate and shaken well.
(9) After centrifuging, the phosphate layer was removed for penicillin assay.

When slide tests were used, twofold dilutions were made with sterile serum. A fraction of serum was added to the first undiluted drop, as staphylococci did not grow in the phosphate buffer solution only. The lowest reading was equivalent to a little over 0·02 unit per c.cm. In the cylinder-plate test, undiluted buffer solution and tenfold dilutions were set up, so that, with the plates seeded with a 1/1000 dilution of the test culture, the lowest reading obtainable was 0·1 unit.

PENICILLIN LEVELS FOLLOWING INTRAMUSCULAR INJECTION OF 100,000 UNITS

All cases had received some kind of prophylactic penicillin therapy in transit, but none had been given any in the 24 hours preceding each experiment, nor was the last dose greater than 50,000 units. In eight instances the assays were done on patients within the first week of wounding, but the wounds of the remainder were considerably older.

The results in 11 cases are recorded in table I. Though cases whose wound-exudate controls did not conform to the standard mentioned earlier are excluded, their blood and urinary assays served to confirm the findings in those described. It will be seen that, irrespective of the age, types of bacteria, or pH of the wound, in every case there was a detectable amount of penicillin in the exudate up to 8 hours after injection, which ranged, at the end of this time, from 0·02–0·32 unit per c.cm.

'1

† An excess of phosphoric acid would probably have been better.

After 12 hours it was still present in 50% of the exudates tested, but beyond this time there was considerable variability between results in different cases. It was noted that, though there were greater variation and prolongation in the duration of demonstrable inhibition in the blood-stream than has been commonly met with in cases treated with this dose (compare Fleming et al. 1944, McAdam et al. 1944, Child et al. 1945), there was a definite correlation between concentrations in the two fluids. Blood- and exudate-penicillin levels were similar at the end of the first hour after injection, but after this the blood-penicillin level fell more rapidly than the exudate-penicillin level—apart from one exception (case 1) there was no instance in which the blood-penicillin level after this time was higher than the exudate-penicillin level. Further, where an inhibitory concentration was prolonged in the blood, it was also prolonged in the exudate.

Urinary excretion of penicillin ranged from 30–50 units per c.cm. during the first 4 hours to 0·0–1·5 units per c.cm. by the end of 24 hours. The 4-hour concentrations were associated with penicillin levels of 0·04–0·08 unit per c.cm. in the blood-stream and 0·16–0·32 unit per c.cm. in the wound exudate. It therefore seems that the penicillin disappears from body fluids after intramuscular injection in the following chronological order: blood, wound exudate, urine.

Possible Factors Influencing Penicillin Assay.—These are discussed here as they apply more particularly to the intramuscular series, for spilling was a larger factor in the local series than any other.

(1) *Blood-urea* estimations were made in each case within 24–48 hours of the assay experiment. In one case (case 2), with a clostridial infection in which inhibition persisted for 24 hours in the exudate and for 12 in the blood, the reading was 360 mg. per 100 c.cm. In the only other case (case 4) in the intramuscular series whose blood-urea could be considered high there was no prolongation of inhibition in the wound beyond 8 hours or in the blood-stream beyond 4. In this case, however, the blood-urea only reached 40 mg. per 100 c.cm. Reduced excretion, as indicated by retention of metabolic products, may have played a part in retaining penicillin in these particular cases but does not appear t affected the others.

(2) The *pH* of the exudates was tested in four of th and in nine of those treated by local instillation. In these it was 8·0–8·4 (case 1). This was one of the c (cases 1 and 5) in which the serous character of the might have influenced the penicillin content (Bigger Inhibition was recorded in the undiluted exudate aft 8 hours in spite of the fact that the blood continued inhibition at a dilution of 1 in 4 at this period. The ing exudates were mainly thin, turbid, and darkly stain blood, with various amounts of deposit, only two purulent, and the eleven tested were within a pH of 6 Destruction of penicillin from this cause therefore have been minimal.

(3) *Bacteria* were looked for in all the wounds. I intramuscular series gram-negative organisms were p in eight and coliforms in five. Four exudates which c coliforms, besides proteus and clostridia, *Staph. alb* non-hæmolytic streptococci in one or another, were at various intervals after known amounts of [illegible] added to them in vitro. One, containing initially 1·0 u c.cm. and assayed by the cylinder-plate test, sustain loss at room temperature of 0·25 unit per c.cm. in an hour of the whole penicillin content after 9 hours. At 3 the penicillin completely disappeared within 4 hours. others had lost more than 0·3 of their original 0·4 c.cm. within 15 min. at room temperature, and the assayed by the slide test and containing initially 0· per c.cm., within 2 hours had lost 0·03 unit per c.cm. at and 0·16 unit per c.cm. at 37° C. Thus, these exudates, contained various organisms—the one in common *Bact. coli*—showed a considerable and rapid loss of pen As a control, a sterile serous wound exudate with a centration of 0·02 unit per c.cm. was set up. It l activity when kept for 24 hours at 4° C, but, on incu at 37° C without penicillin, it produced another inhi factor thus vitiating the comparison.

(4) *Effect of Extraction.*—Eight experiments were either by adding known amounts of penicillin in vitr injection into patients and comparing the assays of the centrifuged and the extracted exudates by cylinder slide test. They showed that little penicillin was lost the extraction, and that in some cases an extract would a value when the merely centrifuged exudate gave an erroneous one or none at all.

TABLE I—PENICILLIN LEVELS AFTER INTRAMUSCULAR INJECTION OF 100,000 UNITS IN 11 WOUNDS

NICILLIN LEVELS AFTER LOCAL INSTILLATION OF 100,000 UNITS

periments were made on eight separate wounds, less than 9 days old, and seven infected with *coli*. A mild pyrexia was present in five cases, all ad previous courses of intramuscular penicillin, and whose control exudates showed a small ring of tion had had local applications 24–48 hours pre-ly. The wound was first cleaned with saline, and a solution of penicillin was inserted, the amount ng with the cubic capacity of the wound. Spilling eakage was inevitable in open wounds during the quent period of observation, thus explaining varia-n results in the same wound. Assays were made by linder-plate method (table II). The extraction method sed in seven cases. Only one reading was taken h experiment, as the quantity of fluid required for est necessitated the emptying of the wound when sample was taken. A fresh instillation of penicillin ch assay was consequently required. As it was n that the original content of the wound was of the of 25,000 units per c.cm., the cubic capacity of the ls being 6 c.cm. or less, it was not considered ary to make early assays. The duration of a able concentration of penicillin was the main at issue, and it will be seen that in all cases this was blood at least 4 hours, for the urine 24, and for the te 48 hours. In 50% of cases tested the duration tended to 6, 48, and 60–72 hours respectively.

s, in this series, the inhibition in the wound out- that in the urine by about 24 hours. These results rrespective of the bacterial flora and the age of the l after 9 days; the pH should not have affected nicillin content; and in no patient was the blood- ver 53 mg. per 100 c.cm. A comparison of the on of inhibitory levels of penicillin by the two ds of administration are set out in table III. It that, though there is very little difference in the on of a detectable amount of penicillin in the blood-, the enormously higher local concentrations from tion into the wound led to a very much greater on of inhibition in both urine and wound exudate.

n attempt to find the amount and frequency of necessary to ensure continuous bacteriostasis in the blood-stream, smaller doses were placed in what suitable wounds still remained to us. Even 33,000 units produced a demonstrable though not necessarily complete inhibitory level in the blood for 5–9 hours. Using this as a basis it should be possible to maintain a constant inhibitory level in the blood by regular instillations of 33,000 units or more.

DISCUSSION AND CLINICAL APPLICATION

The study of these exudates demonstrates the difficulty of reliable assay of penicillin in such fluids. The presence of natural inhibitory factors in pus was demonstrated by Wright et al. (1918). Inhibition has been found by us also in infected pleural exudates and in one instance in a sterile wound exudate after incubation, and by McAdam et al. (1945) in cerebrospinal, peritoneal, and joint fluids. Therefore, before an attempt is made to assay any type of effusion or to estimate its content of penicillin, this source of confusion must be excluded. Extraction provides the best method of doing this, but it lengthens the process of assay considerably. Perhaps the most practicable method would be to control every assay of an exudate by setting up another with penicillinase, and to adopt the more tedious process only if the control shows inhibition.

TABLE III—COMPARISON OF INHIBITION AFTER INTRAMUSCULAR AND LOCAL ADMINISTRATION OF 100,000 UNITS OF PENICILLIN

Source of samples		Minimal duration of detectable penicillin (hr.)	
		Intramuscular	Local
Blood	In all cases tested ..	4	4
	„ 50% „ „ ..	7	6
Urine	In all cases tested ..	20	24
	„ 50% „ „ ..	24	48
Wound exudate	In all cases tested ..	8	48
	„ 50% „ „ .	12	60–72
Range of concentrations detected in wound exudates (units per c.cm.)		2·56–0·02	2000–1·0*

* All at 18 hours or more from instillation.

The most curious anomaly in dealing with these infected exudates was the apparently rapid destruction of penicillin when added to them in vitro and yet its long persistence in the wounds. Possibly in the case of intramuscular injection a continual leakage into the wound from the surrounding tissues might explain its presence, whereas the enormous concentrations used in local instillations would not be significantly reduced by the destruction of several units per hour. Further possibilities are that the rate of destruction varies with the concentration of penicillin, or that adsorption takes place when penicillin is first added to an exudate, with the result that its presence is not demonstrated by the cylinder-plate test. The fact that some penicillin persisted (as shown by the controls) even after an intramuscular course, or the usual local applications of 250 units per c.cm., had been discontinued 24 hours previously, showed its ability to withstand total destruction. Whatever the explanation, the assays appear to be an answer to the fears expressed by some—e.g., Meleney et al. (1946)—that penicillinase-producing bacteria would neutralise the effect of the drug in a wound.

A concentration of 0·02 unit per c.cm. was adopted as the lowest protective concentration; but, though adequate against most staphylococcal and streptococcal invasions, it might be low for clostridial infection. If, however, as Ross (1946) has noted, inhibition of relatively resistant strains depends on the size of the inoculum, then, at an early stage after wounding, when multiplication of bacteria cannot have progressed far, such a concentration should have some effect, for, according to his slide-cell tests, this concentration in circulating serum led to partial inhibition of *Cl. welchii*. Intramuscular injections of 100,000 units produced higher concentrations and complete inhibition for $1^1/_2$–3 hours, depending on the strain used. It can therefore be stated that intramuscular injection of 100,000 units leads to the exudation of a useful level of penicillin into the wound which is reabsorbed more slowly so that protection lasts several hours longer than is indicated by the level of circulating penicillin. Though the results recorded here indicate that, with the dose used, reliance could not be placed on a longer period of inhibition than 8 hours, yet none of these cases was examined during the first 24 hours of wounding, when metabolic disturbances and diminished urinary excretion following severe trauma would favour the retention of the drug within the body. Case 2, with fractures of femur, tibia, and fibula, with much laceration of muscles of the leg and back, *Cl. welchii* in his wounds, a blood-urea of 360 mg. per 100 c.cm., and no excision of his leg wound for 9 days, should have produced very favourable conditions for the development of gas gangrene. Yet inhibition and therefore protection in his case was more prolonged both in blood and wound than in any less severely injured case.

Further application to therapeutic fields may be permissible. If the prolonged presence of penicillin in wound exudates indicates its presence in any inflammatory tissue exudation, a ready explanation is found of the remarkably good results obtained by a course of once-daily injections of aqueous solutions in early syphilis (Jones et al. 1946), and of twice-daily injections in acute inflammatory conditions (Bedford 1946) and in gonorrhœa (Cohen and Grover 1945). It may therefore be feasible to treat purely focal infections by a reduced number of injections per 24 hours—e.g., once or twice—while increasing each individual dose to 100,000 units or more without recourse to vehicles, such as beeswax and peanut-oil, which delay absorption (Romansky and Rittman 1945). Certainly the fears expressed by Rammelkamp and Kirby (1945) of the danger of this type of treatment do not appear to have experimental foundation.

In wounds treated locally, not only the duration of protection but also the concentrations of penicillin make a striking contrast to those treated by intramuscular injection. It might be argued that the assay fluid in these wounds was not a true index of th centration in the tissues of their walls; but, as concentrations were detected in the circulating bl as long as after intramuscular injection, and in the for at least twice as long, clear proof was giv absorption took place. The necessity of coll sufficient amount of exudate for each assay imp use of a solution, but for practical purposes it is that, failing complete suture, full retention of preparation would always be problematical. Thi advantage can be largely overcome by using preparation—powder or tablet. The extraordinar bility and absorbability of penicillin by body renders it an ideal local chemotherapeutic agent. who have used penicillin powder, unmingled with phonamide, in wounds know how rapidly it is and absorbed, though some exudation invariably panies its insertion. So small an area as 1 sq. in absorb 1 g. within a few minutes. Wherever h stasis can be secured, there is no question therefore local implantation of the drug in a wound will surer protection than any practicable intramuscular

One other point of clinical application emerges this study. After intramuscular injection the disap ance of penicillin from the urine succeeded its disapp ance from the exudate, but in the case of local app tion it preceded it. Where wounds need to be enc in plaster, tests of the urine will indicate the presen penicillin placed in the wounds, with a 24-hour mar safety.

The recommendation of intramuscular treatm the routine method of administration of the dr battle casualties, together with the ample supp penicillin available between D-day and the end of th seems to have encouraged the idea among surgeon this is the route of choice for administration. discipline of troops has enabled this method of trea to be carried out effectively and often for a long Though the findings in this paper or the use of ve delaying absorption may enable fewer injections t used, and though oral administration may become p able (Finland et al. 1945, Ross et al. 1945), yet t methods cannot produce concentrations of the comparable with those of local administration focus of infection. To those who have practis seen the results of local administration, only us intramuscular route when inaccessibility of the necessitates it, it has long been obvious that advisedly and repeated at suitable intervals, it n avoids the very undesirable effects of discomfort pain to the patient and disturbance of his rest, b it can accomplish the desired results, both loc systemic, wherever a wound can be so sufficiently either by suture or dressings as to retain the dru

SUMMARY

A method for preparing wound exudates for as their penicillin content is described.

Sources of error from other inhibitory factors and contaminating bacteria are thereby eliminated.

A dose of 100,000 units given intramuscula severely injured battle casualties whose wound 4–61 days old invariably produced inhibition for in the wounds tested, and for 12 hours in 50% of

A dose of 100,000 units given locally into wound days old invariably produced inhibition for 48 ho the wounds tested, and for 60–72 hours in 50% of

These time-limits were irrespective of the age, ba flora, pH, or consistence of the wound exudates.

Blood and urine assays were correlated with findings and served to confirm them.

A possible application of these findings to the t ment of focal infections is mentioned.

advantages of local over intramuscular administra- . prophylaxis and treatment are also discussed.

are particularly indebted to Dr. N. G. Heatley for ıble advice throughout and for carrying out some nents; Dr. J. Humphrey for suggesting the use of nium sulphate in the process of extraction; Lieut.- l J. S. Jeffrey for allowing us to do the work on his Private P. Bowdery for technical assistance; and W. N. L. Ross for some final blood assays.

ORONARY OCCLUSION IN YOUNG ADULTS

REVIEW OF FIFTY CASES IN THE SERVICES

MAURICE NEWMAN
M.D. Lpool, M.R.C.P.
PRINCIPAL MEDICAL OFFICER, MINISTRY OF PENSIONS

THOUGH the last twenty years have seen a rapid lopment in the clinical diagnosis of coronary ısion, it is still considered to be very rare in young ts. A considerable number of cases in patients r the age of forty years have been recorded in the ıture, although most of the authors describe only 2 such cases individually.

uith and Bartels (1932), in reporting 2 cases in patients thirty-five and thirty-six, state that they were able ıd in the literature up to 1932 only 20 proved cases of ıary thrombosis affecting patients under forty years e. Since then many more cases have been recorded. ırant (1937) reports 7 cases in patients aged thirty-five ; or under observed in a clinic in four years. e most extensive series of cases has been recorded by dy et al. (1937), who reported 100 patients under forty s of age, collected from several hospitals and clinics in three ; of these only 8, however, were under thirty years of age. ench and Dock (1944) analysed the clinical and patho- al features of 80 cases of coronary disease in American ers aged from twenty to thirty-six from data received ıe American Army Medical Museum since the beginning ıe recent war. The striking clinical feature was over- ht (in 73 cases), and in every case arteriosclerosis was basic lesion.

ı view therefore of the apparent rarity of coronary mbosis in young people, I have gone through the rds of the Service men and women who have been lided with, or died from, coronary occlusion or mbosis, and collected the records of those up to the of thirty-five for analysis. A careful attempt has ı made to select only those cases where the diagnosis beyond doubt—i.e., either proved by necropsy or re the electrocardiogram shows the characteristic ıges of coronary occlusion in support of the clinical nosis. All doubtful cases have been excluded. ve collected records of 50 such cases which occurred ng the recent war. The youngest patient was . twenty, and no less than 22 of the 50 patients were in their twenties, although as shown below the frequency increases with age, as in the older age-groups:

Age in years	20	21	22	23	24	25	26	27	28	29	30	31	32	33	34	35
No. of cases	1	2	3	1	3	1	1	3	5	2	4	3	6	7	1	7
	7				8				14				21			
	15								35							

These figures show that coronary thrombosis in the young is not so uncommon as was formerly thought, and that it may occur at an early age. Of the 50 cases of coronary thrombosis the diagnosis was established clinically in 11 and by necropsy in 39.

SCOPE OF PRESENT STUDY

I have extracted from the Service documents all the available data that might have a bearing on the ætiology. None of the cases have been seen by me personally. Unfortunately all the information that one would have appreciated—such as family history, ancestral longevity, and habits, including tobacco consumption, &c.—was not recorded. On the other hand, every case was examined on entry into the Service, and in many cases several times subsequently; hence we have a record in every case of the subject's physical condition before the onset of the catastrophe. The occupation before entry into the Service has also been noted. The past illnesses, if any, and conditions of service are usually recorded; and the relation of physical stress to the onset can thus be deduced. The height and weight of the individual on entry is also usually recorded; hence the relation of body-build may also be considered.

CLINICAL FEATURES

Sex-incidence.—Coronary disease at the usual older periods is recognised as being more common in males; in the young age-group of Glendy et al. (1937) the proportion was 24 males to 1 female. In the present series there was only 1 female—a Wren aged 28. It must be remembered, however, that in the pool from which these cases were drawn there were about 10–15 males to 1 female. Even so, it appears that the disease is more common in males than in females in this younger age-group.

Body-build.—The striking feature was the good physical development and nourishment of these young adults. The recorded weight on entry into the Service in 43 of the 50 cases was over 126 lb. The highest weight was 193 lb., and many were over 150 lb. In 21 of the 39 necropsies remarks such as "well nourished," "powerfully built," and "obese" are made. The physical fitness of the subjects is indicated by the fact that 45 of the 50 were graded fit, or I, on entry. Even in the 5 exceptions the lowering of the category was due to some slight disability, such as flat-foot, defective vision, &c., entirely unconnected with the general physical development. The heart was recorded as normal in every case, including those in the lower category.

Previous Infection.—Rheumatic fever may cause proliferation and fibrosis of the elastic tissue of the coronary arteries, with necrosis resembling arteriosclerosis (Karsner and Bayless 1934). Further, acute rheumatic fever is known to cause changes in the electrocardiogram simulating coronary thrombosis. In the present series 3 persons gave a history of rheumatic fever, 2 of them having had the attack only two years before entry into the Service.

There were 2 cases with a history of scarlet fever, and in 1 of them, in which we have a detailed account of the necropsy findings, including histological examination, it appears that the scarlet fever may have been a causal factor in the pathology.

It is now generally recognised that chronic suppuration and infection extending over many years may lead to atheroma. In 1 case in this series the man sustained a gunshot wound of the arm, which necessitated prolonged hospital treatment owing to the formation of sequestra and to low-grade infection. He was discharged from the Service two years later with the wound healed but with albuminuria, and it was stated that he never felt well subsequently. He died two years after discharge from the Service, and necropsy showed "a striking degree of occlusion of one branch of the coronary artery, due to high-grade atheroma, which at this age is a gross abnormality." He was twenty-nine years of age.

It appears, then, that infection may be an ætiological factor in the production of coronary disease in young people.

Physical Strain.—Of the 50 persons, 23, or nearly half, were subjected to physical stress, the catastrophe occurring immediately after the stress in 11 cases and within a few days in the remainder. On the other hand, in 27 cases there was no evidence of any stress before the onset.

Pre-Service Occupation.—Only 8 of the 46 pre-Service occupations recorded were sedentary. Of the non-sedentary occupations about half may be considered as heavy work.

Prognosis.—In the 50 cases there were 39 deaths, a very high mortality. What is equally striking in these young adults is that in 33 of the 39 deaths the persons were found dead or died almost immediately after a collapse. The longest survival period of the 6 exceptions was nine months. In contrast to the high immediate mortality in this series, Connor and Holt (1930) found an immediate mortality of 16·2% in 287 patients of all ages. Boyd (1944) states that less than 25% of patients die in the first attack. It is also noteworthy that practically all the sudden deaths were in apparently fit and healthy men who had previously carried out their military duties without any signs of cardiac distress, the disease being unsuspected during life and only diagnosed at necropsy.

Of the 11 patients still living several have resumed work, although pain on exertion and breathlessness are complained of. As most of the survival cases are of recent occurrence, the ultimate prognosis cannot yet be determined, but 1 patient has so far survived four years since the first attack (syphilis may have been a factor in this case). The only other patient with evidence of syphilis in the series had also resumed work. It may appear, therefore, that the prognosis in syphilitic cases treated appropriately is good, but in view of the small number of cases this is doubtful. In none of the 39 fatal cases was there any evidence of syphilis either clinically or at necropsy.

Necropsy Findings.—The left coronary artery is usually considered as being more frequently affected than the right. In the present series of 39 necropsies the right coronary artery was affected in 5 cases, the left in 17, and both were affected in 16 (no record in the remaining case).

Leary (1941) considers that in the younger age-group of coronary thrombosis (from twenty-two to forty-five) the pathological lesion is due to subendothelial fibrosis, with necrosis of the intima leading to thrombosis. Calcification, he states, does not occur in this group. In the older group (over forty-seven), on the other hand, the fibrotic process is absent and calcification is well marked; thrombus formation is not so common as in the younger group. The findings in this series of 39 necropsies do not support this view. Only 2 of the cases appear to conform to Leary's younger group, showing the fibrotic reaction without calcification. The remaining 37 appear to present the usual degenerative atheromatous changes met with in coronary disease of older people.
In several cases extensive calcification of the
vessels is noted by the pathologist. Again, in
39 cases no thrombus was found.

The heart was definitely stated to be enl
20 cases. In 1 it was described as small. In
myocardial infarction was found, either recent
standing; in 1 case some of the infarcts appear
at least two years old.

DISCUSSION

This series of 50 cases of coronary disease in
adults demonstrates that degenerative change
remarkable degree can exist in the coronary art
an early age, and that coronary disease is not
as formerly thought. It is therefore no longer ju
to disregard the possibility of coronary occlusi
doubtful diagnosis owing to the youth of the
The individuals are usually in excellent health,
physical development, and capable of exertion
any untoward effects. Clinical examination is
negative, and there may be no subjective sym
before the onset.

Whatever the ætiological factors, they appear
more common in males. Body-build appears to
important factor, as most of the subjects were powe
built, robust, and often adipose. There is evidence
in some cases infections, such as rheumatic fever,
fever, and chronic prolonged low-grade toxæmia
play a part in the production of the pathological
in the coronary vessels. Atheromatous lesion
been found in children after acute infections
present series there were 3 cases with a hist
rheumatic fever and 2 of scarlet fever; 1 case fo
prolonged suppuration of a gunshot wound.
appears as infrequent a cause of coronary thro
in young people as in the older age-groups, there
only 2 cases in this series. Hypertension does not
to be so important a factor in this young grou
later life. Only 3 cases showed any evidence of
tension.

Only 8 of the 46 pre-Service occupations were sed
and half of the subjects were doing heavy work
entry into the Service. One might deduce from
figures that sedentary workers suddenly called
experience the stress of Service life were not mor
to coronary disease than manual workers; but
the proportion of sedentary to manual workers
Services is known, any inferences are prematu
unsound.

The high mortality in this series indicates th
prognosis in the young is much worse than in the
age-groups. The immediate mortality is extremel
(33 cases of sudden death out of 39 fatal cases).

In view of the large proportion of sudden
in apparently healthy individuals, the necropsy
are rather surprising. The absence of throm
most cases is unexpected. Again, the fact that
cases the myocardial infarction was due to
occlusion of the coronary vessels by advanced ath
often with calcification, as occurs in the olde
groups, and indicating that the *pathological*
had been present for several years, is also surpri
view of the youth of the subjects.

SUMMARY

A review is given of 50 cases of coronary oc
in young adults in the Services, the youngest
twenty years of age.

The subjects were of good physical developmen
previously fit condition.

Previous infection might have been of ætiol
importance in only a few cases

In more than half the cases there was no eviden
physical strain.

Sudden death took place in 33 out of 39 fatal case

necropsy, 37 out of 39 cases showed the usual
rative atheromatous changes found in coronary
of older subjects, and in 29 there was no thrombus.

ish to thank Sir Walter Haward, Director-General
dical Services of the Ministry of Pensions, for his
sion to publish this paper.

DEFICIENCY DISEASES

RISONERS-OF-WAR AT CHANGI, SINGAPORE

FEBRUARY, 1942, TO AUGUST, 1945

R. C. BURGESS
M.B. St. And., D.P.H., D.T.M. & H.
LAYAN MEDICAL SERVICE; LATELY MAJOR R.A.M.C.,
NUTRITION OFFICER IN THE CAMP

GAPORE capitulated to the Japanese forces on
15, 1942. Of the troops captured, a proportion were
exhausted condition, having fought through a
uous campaign, but the majority had undergone
ively little hardship. In the week that followed
apitulation about 52,000 troops marched out from
pore to Changi Camp—about sixteen miles—in
eat of the day. An outbreak of bacillary dysentery
begun at the time of capitulation, and the shortage
ater and latrine accommodation in the prisoner-of-
camp rapidly resulted in an epidemic in which the
idity-rate was high, but fortunately the disease
due to a mild Flexner infection and the mortality
under the circumstances was low.

GENERAL CONDITIONS

e prisoner-of-war camp was on Singapore Island,
en country near the sea-coast. During the first two
s the area included in the perimeter wire was spacious
allowed considerable movement, but in the last
teen months it was somewhat restricted. Throughout
whole time the housing was inadequate and this was
icularly so in the last eighteen months. The peace-
civil prison was used for housing troops, and 4
were made to occupy cells designed for 1 convict;
building, with its peace-time capacity of 600–700
ners, at times held 6000 men. There were never
gh permanent buildings, and a large number of the
ps were housed in leaf huts with earth floors. These
dark, damp, and impossible to keep clean.

he climate of Singapore is equatorial. The mean
perature is about 80° F, the mean maximum and
imum varying between 87° and 74° F, and the
fall is about 100 inches a year. The temperature
es but little throughout the year and the rainfall
rly evenly distributed. The climate must to some
nt have offset the privations of the prisoners-of-war,
even when the calorie intake was relatively high
did not complain of the heat and during periods of
food intake they complained of the cold only when
ined.

lothing was extremely scarce, especially latterly, and
men wore only a pair of shorts. They worked
whole day in this half-naked state and became a
ogany colour with sunburn.

uring the first year the bacillary dysentery persisted,
about 80% of the personnel had one or more attacks.
ughout the remainder of the time the disease was
ys present and a number of minor outbreaks occurred.
he last year amœbic dysentery became increasingly
mon. In the first two years there was a relative freedom from malaria, but in the last eighteen months some 70% of the total population had one or more attacks.

THE DIET

The Japanese scale of rations for prisoners-of-war was as follows:

Rice	500 g.	Fresh vegetables ..	100 g.
Flour	50 g.	Canned milk ..	15 g.
Sugar	20 g.	Salt	10 g.
Cooking fat ..	5 g.	Tea	5 g.
Meat or fish ..	50 g.		

This scale was not maintained, as can be seen from table I. The details of the diets contained in this table were obtained by averaging the daily issues over a month. Where major changes occurred during the month they are shown.

For the first three years the daily issue of rice, or some substitute, was always more than 400 g. per man. In February, 1945, the first severe cut was made. Men on light duty—i.e., those who were not working for the Japanese or employed on hard work in the camp itself—were given only 325 g. per man per day. This was followed by further cuts, and in the last months of the camp rice was issued in daily amounts of 270, 225, and 180 g. to heavy-duty, light-duty, and no-duty personnel. Almost all the rice supplied was highly milled. The second item in the Japanese scale, a bleached flour, lasted only for the first seven months and did not reappear. The third item, sugar, was maintained at about the 20 g. level throughout the existence of the camp.

The amounts of meat and fish issued varied considerably. Fish was supplied more often than meat. Fresh fish was usually in the form of numerous species of small fish which were exceedingly bony and from which relatively little nourishment could be obtained. The dried fish was in the form of dried sprats (*Stolephorus* spp.), or partially dried and salted horse mackerel (*Caranx* spp.), or, much less frequently, larger dried fish which could not be identified.

Fresh vegetables were not supplied in the first few months, but thereafter sweet potatoes, yams, pumpkin, and cucumber were supplied on a scale exceeding that laid down. Green leaf vegetables in quantity appeared later.

The canned milk on the Japanese scale was supplied only for a little over two months. The last item, cooking fat, was supplied in much more generous amounts than laid down in the scale, except for the first few months.

The diet supplied by the Japanese was supplemented by various means throughout practically the whole period, although the supplements were at times very small. In the first six months or so canned goods, biscuits, &c., which had been brought into camp by our own troops, were issued by the supply depots on a regular scale, but these issues were so small that they were of relatively little value. In October, 1942, Red Cross supplies were brought into the camp and it was possible to supplement the diet very considerably over a period of two and a half months (see table II). In June, 1943, a levy on all money coming into the camp was instituted and the diet was supplemented by purchases of the foodstuffs shown in table I under the heading "Camp Messing Fund."

Estimated Food Value of Diet.—The details are shown in table III. In these calculations no allowance has been made for waste except in root vegetables, although during the periods when food was plentiful there was some waste of rice; in the lean periods waste was reduced to an absolute minimum.

The daily calorie intake in March and April, 1942, was about the 2100 level. It increased slowly, and by August, 1942, had risen to 2500 calories. From then till the end of the third year of imprisonment—i.e., February, 1945—it was usually above the 2500 level.

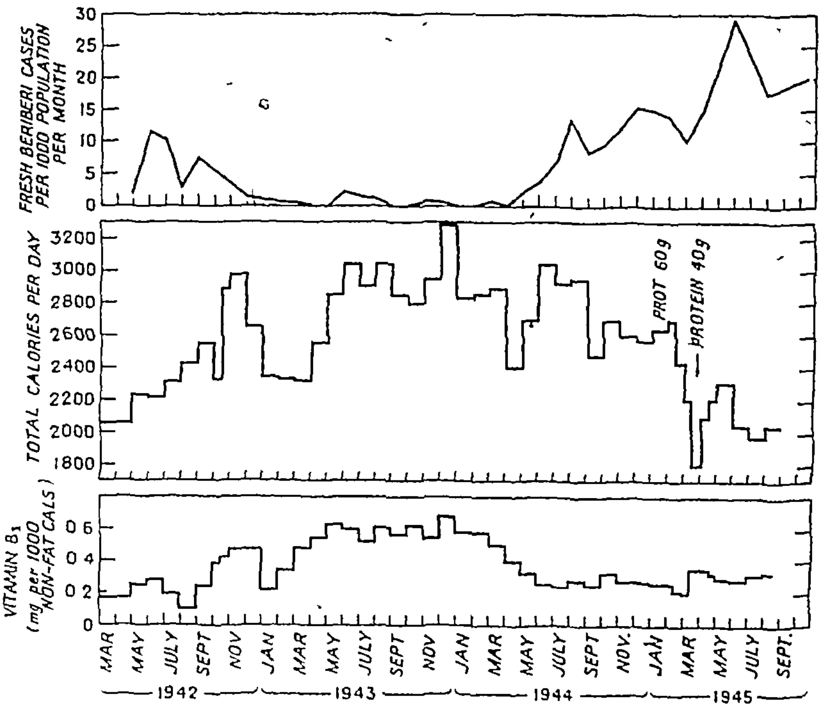

Fig. 1—Monthly incidence of beriberi compared with estimated total calories and vitamin B_1/non-fat-calorie ratio of diet.

During the last six months it fell to 2000 in the heavy-duty scale, 1700 in the light-duty scale, and 1500 in the no-duty scale. Apart from the first few months and the last six months, the calorie intake was not grossly inadequate. The same might be said of the protein content. The fat intake was low for the first few months but thereafter was usually above 50 g. per day. The calcium and phosphorus intakes reached a satisfactory level owing to the dried fish, which was mostly in the form of sprats, and the green leaf vegetables in the diet. Part of the daily ration of cooking-oil was red palm oil, and this together with the green leaf vegetables supplied a high vitamin-A intake. Green leaf vegetables and root vegetables supplied adequate quantities of vitamin C. The diet for long periods was inadequate in several components of the vitamin-B complex. It has only been possible to estimate the vitamin B_1, riboflavine, and nicotinic acid contents, and in all of these there is some deficiency. The position as assessed by estimating the food value of the diet might be summarised as follows. For three out of the three and a half years the energy intake was not grossly inadequate, but for the greater part of the time there was an imbalance in vitamin-B complex. In the last six months there was semi-starvation, with the imbalance, especially of vitamin B_1, still persisting.

In estimating the beriberi-producing potentialities of the diets as prisoners-of-war the formula suggested by Williams and Spies (1938) was used. This formula is *the ratio of vitamin B_1 in the diet to the non-fat calories.* The vitamin-B_1 values given by these writers have been used in the estimations. In comparison with the figures published more recently, these values are low, but, as will be seen subsequently, this method of appraising diets by relating them to the production of beriberi fitted the picture as it occurred in the camp and proved a reliable means of forecasting the incidence of beriberi. It is to be noted, however, that only when the values of Williams and Spies are used can the vitamin B_1/non-fat-calorie ratio of 0·3 be considered as the level at which clinical evidence of deficiency will appear.

The estimated levels of nicotinic acid and riboflavine are shown in table III. Since, with a variation in the
calorie value of the diet from 3
the absolute intakes of nicotin
and riboflavine would be
seemed advisable to relate the
these vitamins to the total energ
they are therefore also shown
grammes per 1000 calories. The
of these three vitamins has been
lated from the tables compiled b
(1945).

BERIBERI

The number of fresh cases of
admitted to hospital per 1000 pop
per month is shown in fig. 1,
vitamin B_1/non-fat-calorie ratio
liams and Spies (1938) and the
total calorie intake. It was clea
the beginning of the camp that
must occur. The estimated daily
vitamin B_1 for the first two month
less than 0·4 mg. and the vitamin B_1/
fat-calorie ratio was under 0·2 mg./
No allowance was made for loss of
vitamin in the preparation and cook
of food, and in the first few
probably 25% was lost in this
bringing the daily intake down to 0·3
Steps were then taken to check th
of vitamin. Cases of peripheral
ascribed to beriberi were admitted
hospital within a month of the start of this imba
diet. All the early cases were in men who had a
history of addiction to alcohol, but the neuritis app
in men with no such history within six weeks.

At this time, as mentioned above, a dysentery ep
was in progress, and some of the patients seven
with this disease developed the superior hæmor
encephalopathy of Wernicke. Treatment and
with vitamin B_1 were eminently satisfactory.

The outbreak of beriberi neuritis was end
November, 1942, by improvement in the diet, and
then until May, 1944, there was a relative freedom
the disease. In the early part of 1944 the vitam
non-fat-calorie ratio began to drop and a furthe
break of beriberi was anticipated. In due cou
appeared (fig. 1), and it persisted *until the camp*

This outbreak may be divided into two pe
(1) from May, 1944, to March, 1945, and (2) from
1945, until the end. During the first period œdem
by far the most common manifestation and in a p
tion of cases was not accompanied by any of the
recognised signs of beriberi. The clinician, ho
was satisfied that this was beriberi, and the re
treatment with the pure vitamin supported b
(Cruickshank 1946). The dietary picture also
that this was the diagnosis. In fig. 1 it will be see
at the end of the first period the calorie intake was
2600 *and the protein* about 60 g. per day. Apart
the chronic dysenterics, no emaciated men were
at this time, and a *representative* group of men
an average loss of only 14 lb. on their weight b
becoming prisoners. These men lost a further 15
the last six months but they still could not have
grossly emaciated at the end of the third year.
the man who got the " beriberi " was not the
chronic dysenteric but the man employed on the
work who would seem relatively fit one day and be
œdematous the next. It can be presumed the
that during this period the symptoms were a mani
tion of vitamin-B_1 deficiency.

In the second period—*March, 1945, to August,*
a new type of case appeared. The clinician
different clinical picture, occurring in the emaciated

sistant to treatment with vitamin B_1. As can be om fig. 1 there was a considerable drop in the and protein intakes. During the last six months lorie intake remained around the 2000 level and otein around 40 g. The vitamin B_1/non-fat-calorie luring this period was still at the level at which oms would be expected, and cases were still ing which were probably beriberi. It seemed that, in the later stages of the camp, two factors producing deficiency symptoms—an inadequate and protein intake; and an imbalance in vitamin nd that while some individual cases appeared to to one or other factor, in the majority both factors l a part in producing symptoms.

sum up, in the first three years vitamin-B_1 deficiency ested itself in the form of œdematous, cardiac, euritic beriberi and as Wernicke's encephalopathy, the last six months, while fresh cases of beriberi ued to occur, the picture was complicated by e œdema.

ring the last few years much experimental work e minimal and optimal requirements of vitamin B_1 een done and there is considerable divergence in timates of these requirements. During the term of sonment, the diet was so deficient in vitamin B_1 symptoms appeared; it then so improved that cases practically ceased to arise; and lastly it deteriorated and fresh cases appeared. This ience might indicate which of the levels for minimal es found by different workers in induced deficiency orrect. But two criticisms might be levelled at this nce. The first is the vitamin B_1 is nated from food s and cannot be as rately known as in experimental study. error, however, is likely to be so great one cannot give a iciently accurate e for the intake h produced disease. second criterion is iochemical investiga- have been possible the more crude rion of clinical obser- on has had to be . On the other hand, number of experi- tal subjects in this ly has averaged 00 over the three and alf years, and since e is a wide individual ation in the utilisa- of vitamin B_1 this number is probably nsiderable advantage leciding the minimal ke. Although dysen- was extremely com- it was usually not severe type, and in 14% of cases in the outbreak were recent cks of this disease ciated with beriberi. the later outbreak aria was common and sibly precipitated beri in some patients. in, the emotional state of the troops at the beginning might by raising their metabolic rate have increased their need for vitamin B_1. All these factors may have affected the findings, but it nevertheless seems profitable to draw conclusions as to the level of vitamin-B_1 intake at which symptoms appear.

The vitamin B_1 content of the diet has been estimated from two food-value tables—those of Williams and Spies (1938) and of Platt (1945). The values given by Platt for the different foodstuffs in question are on the whole somewhat higher than those suggested by Williams and Spies. In their figures Williams and Spies allowed for loss in preparation and cooking, but after the first few weeks the loss in the camp, if judged by present-day views on the destructibility of vitamin B_1, must have been negligible, so estimations based on these data probably give a low assessment of the vitamin B_1 in the diet. Table II shows the vitamin-B_1 intake as estimated from both tables.*

If the incidence of beriberi is related to the vitamin-B_1 intake as estimated from the higher value tables, it will be seen that the disease appeared in about six weeks

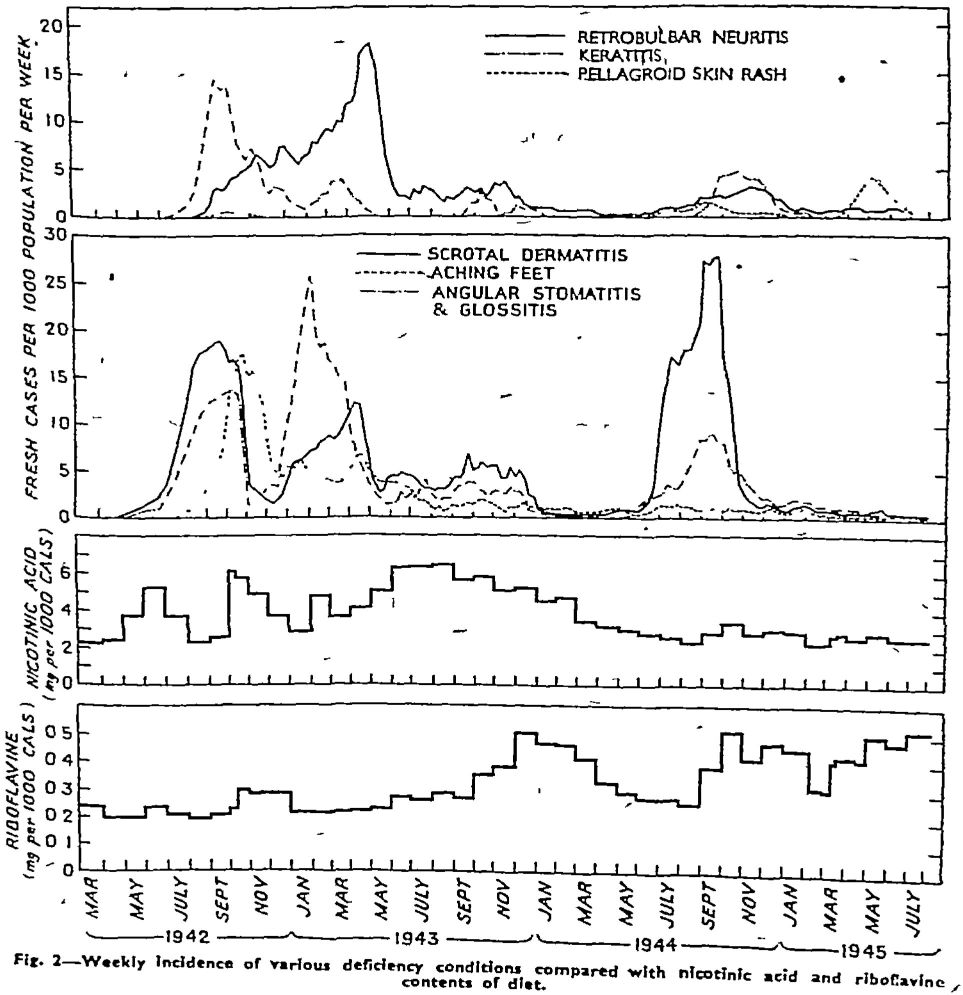

Fig. 2—Weekly incidence of various deficiency conditions compared with nicotinic acid and riboflavine contents of diet.

---

* In table II it will be seen that the total vitamin-B intake reached 1·6 and 1·3 mg. in October and November, 1944. This high level was due to soya bean in the diet. Soya beans, unless processed, are singularly indigestible, and in a prisoner-of-war camp where boiling was the only method of preparation they apparently passed through the bowel unaltered. It seems reasonable to assume that little of the vitamin B_1 was absorbed and that these figures for the B_1 intake for two months were too high. Again, in the last seven months the vitamin B_1/non-fat-calorie ratio estimated by the higher values will be seen to be relatively high. This is due to the high levels attributed to green leaf vegetables, and clinical experience leads one to believe that these figures were again too high.

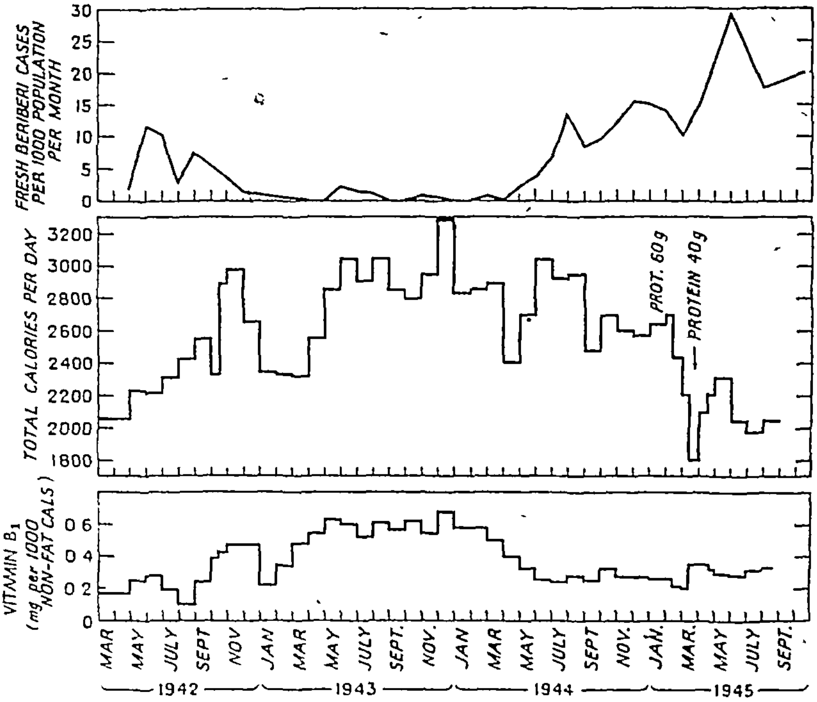

Fig. 1—Monthly incidence of beriberi compared with estimated total calories and vitamin B_1/non-fat-calorie ratio of diet.

During the last six months it fell to 2000 in the heavy-duty scale, 1700 in the light-duty scale, and 1500 in the no-duty scale. Apart from the first few months and the last six months, the calorie intake was not grossly inadequate. The same might be said of the protein content. The fat intake was low for the first few months but thereafter was usually above 50 g. per day. The calcium and phosphorus intakes reached a satisfactory level owing to the dried fish, which was mostly in the form of sprats, and the green leaf vegetables in the diet. Part of the daily ration of cooking-oil was red palm oil, and this together with the green leaf vegetables supplied a high vitamin-A intake. Green leaf vegetables and root vegetables supplied adequate quantities of vitamin C. The diet for long periods was inadequate in several components of the vitamin-B complex. It has only been possible to estimate the vitamin B_1, riboflavine, and nicotinic acid contents, and in all of these there is some deficiency. The position as assessed by estimating the food value of the diet might be summarised as follows. For three out of the three and a half years the energy intake was not grossly inadequate, but for the greater part of the time there was an imbalance in vitamin-B complex. In the last six months there was semi-starvation, with the imbalance, especially of vitamin B_1, still persisting.

In estimating the beriberi-producing potentialities of the diets as prisoners-of-war the formula suggested by Williams and Spies (1938) was used. This formula is the ratio of vitamin B_1 in the diet to the non-fat calories. The vitamin-B_1 values given by these writers have been used in the estimations. In comparison with the figures published more recently, these values are low, but, as will be seen subsequently, this method of appraising diets by relating them to the production of beriberi fitted the picture as it occurred in the camp and proved a reliable means of forecasting the incidence of beriberi. It is to be noted, however, that only when the values of Williams and Spies are used can the vitamin B_1/non-fat-calorie ratio of 0·3 be considered as the level at which clinical evidence of deficiency will appear.

The estimated levels of nicotinic acid and riboflavine are shown in table III. Since, with a variation in the calorie value of the diet fr the absolute intakes of and riboflavine would be seemed advisable to relate the these vitamins to the total they are therefore also shown i grammes per 1000 calories. T of these three vitamins has be lated from the tables compiled b (1945).

BERIBERI

The number of fresh cases of admitted to hospital per 1000 p per month is shown in fig. 1, vitamin B_1/non-fat-calorie ratio liams and Spies (1938) and the total calorie intake. It was the beginning of the camp that must occur. The estimated vitamin B_1 for the first two month less than 0·4 mg. and the vitamin B_1/ fat-calorie ratio was under 0·2 No allowance was made for loss of vitamin in the preparation and of food, and in the first few probably 25% was lost in this bringing the daily intake down to Steps were then taken to check the of vitamin. Cases of peripheral ascribed to beriberi were admitt hospital within a month of the start of this imb diet. All the early cases were in men who had a history of addiction to alcohol, but the neuritis in men with no such history within six weeks.

At this time, as mentioned above, a dysentery was in progress, and some of the patients seve with this disease developed the superior hæm encephalopathy of Wernicke. Treatment and prop with vitamin B_1 were eminently satisfactory.

The outbreak of beriberi neuritis was en November, 1942, by improvement in the diet, a then until May, 1944, there was a relative freedom the disease. In the early part of 1944 the vita non-fat-calorie ratio began to drop and a furth break of beriberi was anticipated. In due appeared (fig. 1), and it persisted until the camp

This outbreak may be divided into two (1) from May, 1944, to March, 1945, and (2) from 1945, until the end. During the first period œde by far the most common manifestation and in a tion of cases was not accompanied by any of th recognised signs of beriberi. The clinician, was satisfied that this was beriberi, and the re treatment with the pure vitamin supported (Cruickshank 1946). The dietary picture also that this was the diagnosis. In fig. 1 it will be se at the end of the first period the calorie intake wa 2600 and the protein about 60 g. per day. Ap the chronic dysenterics, no emaciated men we at this time, and a representative group of men an average loss of only 14 lb. on their weight becoming prisoners. These men lost a further the last six months but they still could not ha grossly emaciated at the end of the third year. the man who got the " beriberi " was not the em chronic dysenteric but the man employed on the work who would seem relatively fit one day and be œdematous the next. It can be presumed th that during this period the symptoms were a ma tion of vitamin-B_1 deficiency.

In the second period—March, 1945, to August, a new type of case appeared. The clinician recog different clinical picture, occurring in the emaciat

tant to treatment with vitamin B_1. As can be
a fig. 1 there was a considerable drop in the
ıd protein intakes. During the last six months
ie intake remained around the 2000 level and
in around 40 g. The vitamin B_1/non-fat-calorie
ing this period was still at the level at which
ıs would be expected, and cases were still
; which were probably beriberi. It seemed
hat, in the later stages of the camp, two factors
oducing deficiency symptoms—an inadequate
nd protein intake; and an imbalance in vitamin
that while some individual cases appeared to
ɔ one or other factor, in the majority both factors
part in producing symptoms.

n up, in the first three years vitamin-B_1 deficiency
ed itself in the form of œdematous, cardiac,
ritic beriberi and as Wernicke's encephalopathy,
he last six months, while fresh cases of beriberi
ed to occur, the picture was complicated by
edema.

in April, May, and June, 1945, were supplemented with food from Red Cross parcels. The amounts were very small—about 10 g. per man per day of chocolate, jam, bully beef, &c.

Details of the light-duty and no-duty scales introduced in February and April, 1945, respectively, have been omitted owing to lack of space.

C.M. Fund = Camp Messing Fund

on a daily intake of 0·2 mg. per 1000 non-fat calories (N.F.C.) or a total intake of 0·39 mg., and that fresh cases ceased to occur when the daily intake rose to 0·5 mg. per 1000 N.F.C. or a total of 1·2 mg.; a further outbreak started when the daily intake fell to 0·36 mg. per 1000 N.F.C. or a total of 0·9 mg. If the levels are estimated from the lower figures, the disease appeared in six weeks on a daily intake of 0·18 mg. per 1000 N.F.C.; fresh cases ceased to arise when the intake reached 0·47 mg. per 1000 N.F.C.; a further outbreak occurred when the intake dropped to 0·26 mg.: and fresh cases kept appearing as long as the intake was below 0·3 mg. and even when it reached the higher level of 0·33 mg. per 1000 N.F.C.

In deciding whether a diet is beriberi-producing, a vitamin-B_1 intake of 0·3 mg. per 1000 N.F.C. should be regarded as an absolute minimum and if the higher values of the more recent food tables are used 0·4 mg. is probably the minimum. This experience suggests that the 0·37 mg. per 1000 N.F.C. found to be adequate for normal carbohydrate metabolism in experimental conditions by Keys and colleagues (1943) is inadequate to prevent cases of disease appearing in a large group. There was a great individual variation in susceptibility to beriberi which might be accounted for by variations in the requirement of vitamin B_1 for carbohydrate metabolism or possibly by varying degrees of biosynthesis (Najjar and Holt 1943). Whatever the reason, this experience supports the views of Williams and colleagues (1943a), who, on the evidence of induced deficiency, concluded that the much more liberal allowance of 0·66 mg. per 1000 N.F.C. is a minimum intake to maintain normal carbohydrate metabolism.

DISEASE DUE TO DEFICIENCY OF VITAMIN B_2

The following disease conditions appeared in the camp: angular stomatitis, glossitis, palatal erythema, scrotal dermatitis, pellagroid skin rash, aching feet, spastic paraplegia, keratitis, retrobulbar neuritis, and nerve deafness. The incidence of fresh cases of six of these conditions per 1000 susceptible population per week is shown in fig. 2. The incidence of spastic-paraplegia and nerve deafness is not shown in graph form. Since only about 40 cases of spastic paraplegia occurred in the camp, all within the first eighteen months, the incidence per 1000 population was so low that it cannot readily be shown in a graph. They occurred at a time when the incidence of other conditions, such as sore feet, was at its highest. The incidence of nerve deafness was high, but it was often not noticed by the sufferer until his friends drew attention to it, so a record of the fresh cases would not give a true picture of the outbreak.

It can be seen from fig. 2 that there were two periods of fairly high incidence of these diseases, and during the remainder of the time there was a relative freedom from them. There were also two outbreaks of beriberi, but the first was small and of short duration and occurred early. The first outbreak of the diseases now under discussion was large, extended over a long period, and appeared later. The second outbreak of beriberi was protracted and larger, while the later outbreak of the other disease conditions was of short duration and—for some of them—of much smaller dimensions. It is clear that there is little similarity between the trend of incidence of beriberi and any of these other disease conditions.

The clinical picture of the commoner conditions answers in the main to the descriptions given elsewhere. The keratitis was the disease described by Métivier (1941) as "corneal epithelial dystrophy."

Time Distribution.—There are some points of interest in the relative times of appearance and of highest incidence of these conditions. The first evidence of disease appeared early in May, 1942—about two and a half months after the capitulation and one and a half months after the first cases of beriberi appeared. The glossitis and angular stomatitis and scrotal dermatitis the first to appear; next came aching feet at the July, 1942, nearly three months later—i.e., five and months after the capitulation. Keratitis and retro neuritis appeared at the middle and end of A respectively. It will be seen that there is a tende follow this trend throughout. In October and Nov 1942, the incidence of mouth conditions and dermatitis showed a sharp decline; the decline of feet was slower and less definite, and there wa evidence of any change in the slowly rising incid retrobulbar neuritis. In the subsequent incre January and February, 1943, this order was followed, though not so definitely. At this time was a rapid increase in mouth conditions and a rapid increase in scrotal dermatitis. Aching fee keratitis showed a slowly increasing incidence did not reach any height. In 1944 scrotal de and mouth conditions again showed a rapidly r incidence, starting at the end of May and be June, while keratitis began to increase in Au Aching feet were not much in evidence at this time, though there was a rise in the incidence of retrobul neuritis, it began earlier and did not reach a high le

There is then some evidence of a relationship betw all these conditions as regards the beginning and e of outbreaks and they appear to fall into three group

1. Mouth condition and scrotal dermatitis.
2. Keratitis and aching feet.
3. Retrobulbar neuritis.

There are, however, some features which do not fit this picture—the persistence of a high incide scrotal dermatitis in March and April, 1943; the rising incidence of retrobulbar neuritis before disease conditions had appeared in 1944; and absence of a clear-cut outbreak of aching feet at time.

The high incidence of scrotal dermatitis might p be accounted for by the fact that when a deficiency exists the devitalised tissue is particularly susc to the action of any irritant or to invasion by ba and in this case a particularly irritant soap or la facilities for washing may have been responsible. explanation for these other phenomena springs t mind.

The other disease condition shown on the c pellagroid skin rash—appeared twice during out of the diseases just discussed, but the largest out began in the early months of 1945 when these deficiency conditions were almost absent.

Relation to Nicotinic-acid and Riboflavine In Fig. 2 ‡ shows that all these conditions, except pella skin rash, were common when the riboflavine leve low and outbreaks came to an end when it reach higher levels. On the other hand, only the pe skin rash bore any relationship to the estimated ni acid content of the diet, its appearance coincid a low intake of nicotinic acid, though it did not sistently appear when the intake was low. This was a mild one, appearing almost entirely in men w in the sun, so it seems that frank clinical evide disease only manifested itself under certain c conditions with this degree of nicotinic-acid defic

---

† Woodruff, M. (unpublished data), after correlating info concerning associated conditions, concluded that de disease in the Changi Camp could be divided into two g (1) a beriberi (B_1-deficiency) group, and (2) the remain B_2-complex-deficiency group. He pointed out that 49% cases of peripheral neuritis showed other evidence of while in only 5% of the disease conditions in group 2 wa an association with beriberi. Of over 1000 cases of retr neuritis, 36% had keratitis, 20% aching feet, and 23% titis and glossitis, while only 1% had beriberi. Of cases of aching feet, 31% had retrobulbar neuritis, 29% titis, and 24% scrotal dermatitis, while 7% had an as beriberi.

‡ The scale in this figure is based on the relative requireme laid down by the National Research Council of America.

ays of the camp but it proved of little value
ical use and was abandoned as a means of
laxis.

bout eighteen months in the existence of the camp
rom November, 1942, until May, 1944—by pooling
coming into the camp and by purchasing and
foodstuffs rich in vitamin B_1 on a fixed scale
t was maintained above the beriberi level. In
under the heading "camp" the details of food
sed can be seen. In the last year the money for
sing foodstuffs was less and the prices were
ically high, so little could be done to supplement
balanced and latterly inadequate diet. When the
ese learnt of their country's capitulation they
as much rice as was wanted. The consumption
e quantities of rice at this time would have led to
grave imbalance, resulting in severe beriberi. A
stand was taken in this matter, and after some
t it was agreed to restrict the daily issues of rice
evel which would not cause a serious imbalance.
nately this period was short, and with the arrival
ieving troops the prisoners-of-war went back to
opean diet.

Vitamin-B_2-deficiency Disease.—The minor manifestations in the syndrome referred to as vitamin-B_2-deficiency disease in this paper were believed to be due to a riboflavine deficiency. There was a significant association between disease conditions in this group, and no such association could be found between them and beriberi. In addition, the commencement, course, and cessation of outbreaks led us to think that, excepting pellagroid skin disease, they probably had a common ætiological factor.

The policy in prevention was based on raising the riboflavine value to the highest possible level. Some tables of riboflavine values were available in the camp, but they were old and judged by the more recent tables highly inaccurate. They did indicate however that, of the limited foods available, fresh green leaves and légumes were the only ones which could be obtained in sufficient quantity to be of value. This was the reason for the main items in the supplementary foodstuffs purchased.§

§ The other foodstuffs were introduced for the following purposes: (*a*) The rice polishings were to ensure the absence of beriberi and also to raise the nicotinic-acid level. (*b*) The palm oil was to increase the calorie intake and make the food more palatable. (*c*) The dried fish, preferably sprats, was to maintain at a reasonable height the calcium and protein intake.

Since some of these conditions are probably manifestations of riboflavine deficiency the estimated levels of intake at which symptoms appeared are worthy of note. On an estimated level of 0·21–0·25 mg. per 1000 calories, symptoms appeared in two and a half months in 1942; in 1944, on an intake of 0·33–0·28 mg. per 1000 total calories, this appeared in about the same time. It is not clear, on the basis of our estimated levels, why the number of cases should have fallen in October, November, and December, 1942. The improvement was due to Red Cross supplies coming into camp. For purposes of estimation, the diet during the period under discussion was assumed to be in accordance with the advice given on how the extra food should be consumed; but, since it was distributed to units and in some cases to individuals, the extra food may in fact have been consumed more rapidly with a resultant higher intake over a shorter period.

In fig. 2 it will be seen that a fresh outbreak of keratitis occurred in October, November, and December, 1943, at a time when the riboflavine values of the diet were higher than they had been, and there is evidence of a similar rise in the other conditions. In August the Japanese began making a big aerodrome near the camp and labour was drawn from the camp. Labouring in the heat of the day and in the full glare of the sun may have played some part in producing this increase.

In general the estimated intake of riboflavine corresponds fairly closely with the incidence of disease, so it seems worth while to compare the level at which disease occurred with similar levels found by workers in induced deficiency. Sebrell and colleagues (1941) produced deficiency disease which appeared between the 89th and 232nd days on a riboflavine intake of 0·21 mg. per 1000 total calories. This is in line with experience in the camp where disease developed in 80 days on an intake of 0·21–0·25 mg. per 1000 calories. Williams and colleagues (1943b) found no deficiency disease on an intake of 0·35 mg. per 1000 calories. In the camp disease persisted on this level although it had begun on a lower intake and on two occasions the outbreak of disease did not end until the level reached 0·5 mg. per 1000 calories. This would support the suggestion of Williams and colleagues that 0·5 mg. per 1000 calories is an adequate intake.

There were further experiences which have some bearing on this point. In 1943 a party of 7000 men went up country and 25% of them had vitamin-B_2 deficiency in one or more of the forms which have just been discussed. They went up to conditions of starvation, disease, and appalling hardship, and at the end of nine months when 44% had already died they were returned to the Singapore camp. Within a week or two of leaving the relative comfort of the camp the minor manifestations of vitamin-B_2-deficiency disease disappeared and did not recur as long as the conditions of hardship lasted. Little or no retrogression in cases of retrobulbar neuritis could be found on their return. The calorie intake during this expedition was at times as low as 1200 per day although it was at other times above the 200 rapid loss of weight occurred. The Japanese merciless in their demands for output of work, itself was the direct cause of a number of deaths. diets consisted of rice and very little else, and the ri- flavine intake for long periods was about 0·2 m 1000 calories; for about a month in one camp it low as 0·15 mg. per 1000 calories.

When a man is consuming his own tissues his for riboflavine may be less, and this idea led investigate the relative incidence in different gro men in Changi Camp. In the kitchens and food sto men were better fed; hungry men cannot be ex- to handle food all day without taking a certain of it. On the other hand the men working on the aerodrome got only their bare rations and were cal for a greater energy output. In the better fed grou incidence of scrotal dermatitis during an outbreak 34% and in the worse fed group it was only 18% were several hundred men in each sample and unfo nately weights were not taken, but had they been th is little doubt that there would have been a clearer difference. The impression gained was that rib deficiency was essentially the disease of the man who *maintaining or gaining weight.* The pellagroid skin r on the other hand occurred essentially in emaciated m In some 60 men treated for skin rash in hospital average weight was 102 lb., while a group of fit men the same period had an average weight of 125 lb

PREVENTION OF DEFICIENCY DISEASE

In the prevention of deficiency disease beriberi w always regarded as being of primary importance, fo is a killing disease. The vitamin-B_2-deficiency dis- though they seemed likely to be responsible for a siderable amount of permanent incapacity, were portant as a cause of death. Steps taken to pre beriberi built up the diet to a greater or less exte components of the vitamin-B_2 complex and measures taken had both purposes in mind. It advisable, however, to deal with each separately

Beriberi.—The occurrence of beriberi was fore some time before it actually appeared, and atte were made immediately to minimise the danger. best means of doing this was of course to enrich the and in March, 1942, the G.O.C. Prisoner-of-war Ca Changi, wrote to the H.Q. Imperial Japanese A pointing out that the diet was grossly deficient in ce vitamins and asking for additional foodstuffs which known to be in Singapore in considerable qua The Japanese did nothing, although the case presented again and again in the early months.

A measure which was adopted early and to wh considerable attention has been paid throughout the preparation and cooking of food so that none of vitamin content was lost. This is particularly impor in the case of the rice. The ordinary highly milled has about 0·5 μg. vitamin B_1 per g. in the pericarp and fine layers of pericarp that may remain after mi It is however *readily soluble in* water, and if it is wa and the water discarded about half of it is lost, a if it is boiled in excess of water which is afterwa discarded there is a further loss. Seeing that at time total daily intake of vitamin B_1 was not more than 0·4 and that 0·2 mg. came from rice, the importance of measure can be appreciated.

A measure which is widely advocated for preven beriberi is the growing of yeast, but unfortunately yeast is grown on a medium rich in the vitam complex it has little capacity to synthesise this vitam In fact recent work (Malm 1945) suggests that it does synthesise it at all but simply captures it from medium in which it is grown. Yeast was grown in ie and Mollison (1943) may reveal the group while cells are still present. There are times when nportant to know the nature of a patient's cells, complete typing has not been carried out before the ition of a line of treatment which has falsified the picture. Such a case was seen recently at this al, and it was considered that investigation of the marrow red cells, which are not subject to the same ement by donor cells as are those of the peripheral , might establish the true blood-group. As no nce to the reliability of bone-marrow grouping could md in the available literature, normal children were as controls at the same time.

INVESTIGATION

rrow was obtained from twelve children who had no transfusions and in whom marrow puncture being undertaken for diagnostic purposes.

e first two marrow samples were taken from the m with an ordinary Salah needle. As, however, ield of sternal marrow was rather too small for the se, particularly in small infants, and rendered r oxalating of the sample difficult, the later punc were made through the flat area of bone internal istal to the tibial tuberosity. Needles, used accord o the size of the patient, were those designed by on (1944) for marrow infusions.

rrow was aspirated into a syringe, from which it was ediately expelled into a small test-tube containing le oxalate mixture (3 parts of ammonium to 2 parts otassium oxalate) which had been allowed to dry then moistened with a drop of normal saline just re use. If the oxalate was used dry, various degrees glutination jeopardised the chances of satisfactory ping. Only marrow discharged direct into the ate was used, any adhering to the side of the tube g carefully avoided.

arrow suspensions so obtained were ABO- and Rh- d in small tubes in the ordinary way.

RESULTS

ll twelve marrows showed the same ABO agglutino- s and agglutinins as those found in their corresponding imens of blood. Similarly, no difference was found he Rh genotypes of marrow and peripheral blood from same patient. The presence of nucleated red cells the myeloid series did not interfere with reading test.

rom these results it appeared that the true blood- up and Rh genotype could be ascertained from the row cells. Therefore marrow grouping was under- en at intervals on the patient whose peripheral d could not be grouped owing to repeated blood- sfusions. The following hæmatological findings are en in detail to illustrate how the divergent blood marrow pictures came into line again as the donor s were eliminated.

aby X, with erythroblastosis fœtalis, was the second d of healthy parents, whose first child was normal. Baby X born on Feb. 20, 1946, and became jaundiced on the 1. Blood-group A, β in the serum, Rh-positive.

he mother, blood-group A, Rh-negative, had a low Rh ibody titre at birth of the baby, and a titre of 1/64 on ch 2, 1946, and 1/256 on March 5, when some blood was en from her for preparing anti-Rh serum.

etween Feb. 24 and April 5 the baby received eight trans- ons of whole blood with group-O Rh-negative blood, the in red-cell count after each transfusion being only transient. the meantime the mother's blood had been processed by s B. E. Dodd, who reported that it contained antibodies he Rh factors C and D.

n April 6, to cross-check this finding, the baby's blood was genotyped and found to be Rh-negative. Also, the O group, which was put up as a routine, was O, with neither or β demonstrable in the serum.

esults were the same on April 7, except that weak β was present in the serum. This reversal of group with β in the serum was also confirmed by Miss Dodd on April 8, though at birth the baby had group-A Rh-positive blood.

From April 5 to 18 the baby slowly lost its red cells, the count falling from 4,700,000 to 4,280,000 per c.mm. On the 18th the peripheral blood-cells were group O, with β in the serum, and there was a trace of agglutination with anti-D serum. In the marrow, on the other hand, the cells were group A and Rh genotype CDe, cde.

As marrow smears at this stage showed only 2·5% of primitive red cells, it was apparent that the repeated transfusions were producing a condition of red-cell hypoplasia, and further transfusions were withheld in the hope that the marrow would be stimulated to make its own cells.

On April 25 the peripheral red cells were grouped as A, with a good anti-D reaction but no agglutination with anti-C serum. On the 27th the blood-count had fallen to 3,530,000 per c.mm., and the blood antigens were A CDe, cde, a formula corresponding to that in the marrow.

These results are summarised in the accompanying table. Since then, the marrow has produced 12% of normoblasts, and the red-cell count is slowly rising. In the meantime the father, group A, has been genotyped as CDe, cDE.

CHANGES IN THE BLOOD

Date	Antigens present	
	Blood	Marrow
Feb. 25 ..	A Rh +	..
April 5 ..	O cde, cde	..
April 6 ..	O cde, cde	..
April 7 ..	O cde, cde	..
April 18 ..	O cDe, cde	A CDe, cde
April 25 ..	A cDe, cde	A CDe, cde
April 27 ..	A CDe, cde	A CDe, cde

DISCUSSION

It is clear from the twelve normal controls that the bone-marrow red cells contain the same hæmagglutinogens as do the peripheral cells. Also, the case illustrated demonstrates that, where frequent transfusions have been given, the marrow cells, being in a sense fixed, may reveal the true antigens when the peripheral blood-group is either obscured or altered by donor cells.

In the present case there was no indication at birth to genotype the baby, which was merely recorded as Rh-positive. As the father was CDe, cDE, and the mother made anti-C and anti-D agglutinins, there cannot be much doubt that the infant was originally a CDe, cde, a typing confirmed by the marrow and to which the peripheral blood eventually reverted. As the father was not available when the baby's blood was giving an untrue picture, the marrow reaction gave valuable corroborative evidence about the type of agglutinins present in the mother's serum.

The behaviour of β suggests that the original antibody was obtained from the mother, its disappearance and reappearance coinciding with its obsolescence and the baby's starting to manufacture its own β.

The return of the antigens to the blood showed some odd features. That the Rh antigen was detectable before its ABO counterpart was probably due to the use of higher titre anti-Rh sera; but why D should reappear before C was demonstrable with high-titre serum is not so clear, if the fixity of antigens is accepted, and may be due to the fact that the factor D as a rule seems to be more readily agglutinable than either C or E.

I am indebted to Dr. Donald Paterson for access to the patient, to Miss B. E. Dodd for her help with the sera, and to Mr. G. W. Cecil for much technical assistance.

Wiener, A. S., Sonn, E. B. (1946) *Amer. J. Dis. Child.* 71, 25.

The amounts arrived at were as follows:

Rice polishings	30 g.
Palm oil	30 c.cm.
Green gram (*Phaseolus radiatus*)	100 g. in all
Ground-nut	
Soya bean	
Sprats or dried fish	50 g.

The camp food tables indicated that the green gram, *Phaseolus radiatus*, had an unusually high riboflavine content while that of soya bean was low. The more recent tables show the reverse, but in view of our information the green gram was always purchased in preference to the other légumes. It will be seen from fig. 2 that the riboflavine level of the diet did not reach any great height until December, 1943, and from table I it will be clear that the cessation of the outbreak of vitamin-B_2-deficiency disease was probably due to the introduction by the Japanese of 170 g. of soya bean in place of an equal amount of rice.

The importance of green leaf vegetables in the diet was appreciated by the British administration in the camp, but, for the first two years, the Japanese were either indifferent or could not be made to understand that much sickness could be avoided if they would allow the proper cultivation of vegetable gardens. At the end of the second year a new Japanese commandant was more intelligent about the matter and good vegetable gardens were made. From September, 1944, until the end of the camp these gardens were probably responsible for our freedom from these diseases. In fig. 2 it will be seen that the riboflavine content was higher in that period.

Since no green leaf vegetables were available at the time of our greatest need and légumes were not obtainable in the required quantities, at the beginning of 1943 it seemed worth while to try to extract the vitamins from some of the non-edible plants and grasses growing round the camp. Fortunately power was available and the engineers built various ingenious devices for crushing leaves so that their cellular structure was broken down. They were then macerated with water and the extract was drunk. As long as fresh rapidly growing structures were available the results obtained from this extract were excellent, but soon the area to which the prisoners-of-war had access was cleared of all such plants. Coarse tropical grasses were then used and little benefit appeared to be derived from the extract.

SUMMARY

An outline is given of the general living conditions in the prisoner-of-war camp on Singapore Island. The Japanese ration scale and the supplements that could be procured are described.

Estimation, week by week, of the composition of the diet showed that the energy and protein intakes were not grossly inadequate except in the last six months, but there was throughout a deficiency of one or more of the B vitamins.

There were two outbreaks of beriberi. The first, which occurred early, was uncomplicated but in the second the picture was confused by famine œdema.

Comparison is made between the minimal levels of intake of vitamin B_1 to prevent disturbance of metabolism, as defined by workers on induced deficiency, and the estimated levels at which beriberi appeared or disappeared in the camp. It is concluded that the higher limits proposed on the basis of experimentally produced deficiency (0·66 mg. per 1000 non-fat calories daily) are in best agreement with experience in the camp.

The order and times of appearance of disease conditions attributed to deficiency of one or more components of the vitamin-B_2 complex are compared with those of beriberi and with the estimated riboflavine and nicotinic-acid contents of the diet. They appeared and disappeared in a definite sequence, independent of and with an inverse correlation with the n intake, except pellagroid skin rash which showed relationship to the intake of nicotinic acid.

The requirements of riboflavine as defined by w in induced deficiency are compared with the levels in the camp diet. The level required to deficiency as suggested by the camp diet is simi the findings of some experimental workers, and experience again supports the higher suggested levels (0·5 mg. per 1000 total calories daily).

Of 7000 men who left the camp to work up the more than a third had signs of vitamin-B_2 defici camp, and they subsequently suffered so severely starvation and disease that 44% died within months; yet under these conditions the signs of vi B_2 deficiency, except retrobulbar neuritis, disapp Further, vitamin-B_2-deficiency disease in camp commoner in the relatively well-fed men. Pella skin rash, on the other hand, was more often fou the emaciated.

The means used in attempting to combat defic diseases in the camp are briefly described

I wish to thank Lieut.-Colonel Kenneth Alford, I.M and Major R. Orr, A.A.M.C., for their coöperation in t prisoner-of-war camp, and Dr. Isabel Leitch, Rowett Res Institute, for her help and criticism in the preparation of paper.

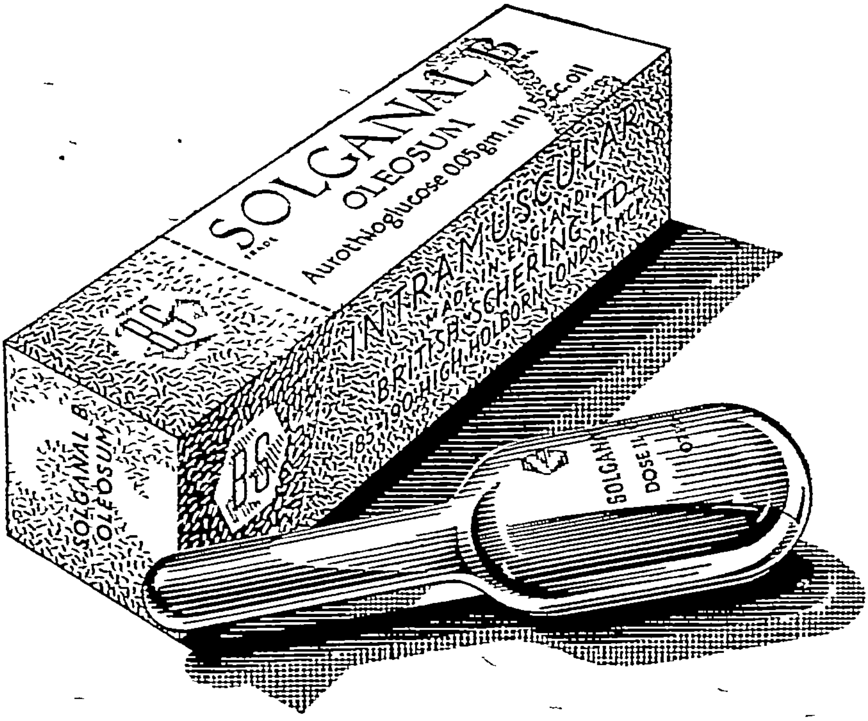
BLOOD-GROUPS IN BONE-MARROW

I. A. B. Cathie
M.D. Lond.
CLINICAL PATHOLOGIST, HOSPITAL FOR SICK CHILDREN
GREAT ORMOND STREET, LONDON

"The fact of belonging to a definite blood gr a fixed character of every human being and can be al neither by the lapse of time nor by intercurrent dis (Lattes 1932). This statement on the fixity of t groups may be said to represent the present cons of opinion.

With the modern tendency to give repeated transfusions in various conditions, however, r ment of the patient's red cells with donor's cells that part of the patient's peripheral blood will eve characters of the donor's cells. Should the donor carry different *hæmagglutinogens* from those of recipient, anomalous results will be obtained attempting to establish the patient's own group cases are on record where all the patient's cells had replaced and only the group of the donor coul ascertained from the patient's blood. In such a an apparent, though not real, change of blood g may be found. For example, the blood of case II Coombs et al. (1946) appears to have been ent replaced; and case 4 of Wiener and Sonn (1946) an erythroblastotic infant whose Rh-positive cells w entirely replaced by Rh-negative donor cells wi two days.

Hitherto, in establishing the true group of such c there has been little option but to wait until the do cells have disappeared; though, as the patient's start to reappear, the differential agglutination met



No Shortage Now

Supplies of SOLGANAL B OLEOSUM are now adequate to meet all demands. This detoxicated gold preparation in oily suspension—slowly absorbed, gradually excreted and remarkably free from toxic sequelæ—is supplied in ampoules of 0·01, 0·02, 0·05 and 0·1 gm. in line with the most recent clinical reports. New literature which deals objectively with chrysotherapy most gladly sent on request.

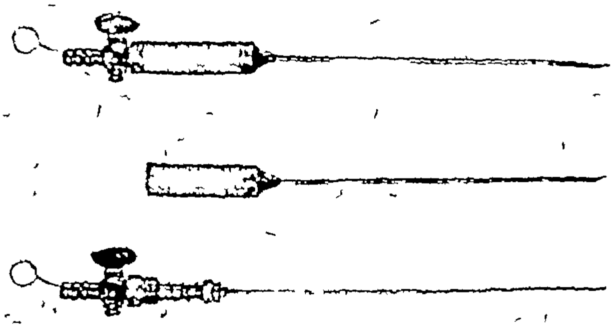
PNEUMOPERITONEUM-REFILL NEEDLE

THE induction of a pneumoperitoneum is much more difficult in most cases than that of an artificial pneumothorax, because, owing to the softness of the abdominal wall, it is extremely difficult to be certain when the point of the needle is within the peritoneal cavity. Again, in the pleura a good negative pressure is usually found, except when the pleura is adherent, whereas in the peritoneal cavity the pressures are often difficult to record because: (1) they are not so great as in the pleural cavity, and (2) a loop of intestine or a piece of omentum may obstruct the hole in the needle.

The needle described was designed by Veress, in Switzerland, to get over these difficulties. It is extremely simple to use and very efficient. The point of the needle is formed by a strong, hollow, but blunt trochar running within the needle, with an exit hole at one side, just below the blunt end of the trochar. The distal end of this trochar is fitted with a spring so that it projects about 1 mm. beyond the point of the needle, but can be withdrawn within the needle, being pushed out again by the spring when released. When the needle is pushed through the tissues of the abdominal wall, the blunt trochar is pushed back against the spring, and the cutting edge of the needle, within which it runs, pierces the tissues easily, the spring pushing the blunt trochar forward as soon as the peritoneal space is reached, displacing the gut or omentum in front of it, but not damaging it, as the trochar is blunt. A swing on the manometer may or may not be recorded, but it is quite safe to allow air to run in at this stage, at the end of which the pressures will be easily recorded.



Above, the needle assembled for use. Middle, the cannula. Below, the spring and trochar.

The technique in actual experience is helped by the following suggestions. After anæsthetisation of the skin and parietal peritoneum in the usual way, the needle is inserted much more easily if a small nick is made in the skin just medial to the lateral border of the rectus at about the level of the umbilicus. As the needle is pushed forward, the blunt trochar is pushed back against the spring as it pierces the external fascial layer of the sheath of the rectus abdominis, but springs forward as soon as this is pierced. As the needle is pushed forward slowly, the blunt trochar is again pushed back as the internal layer of the sheath of the rectus abdominis is encountered, the trochar springing forward again when this is pierced. These two movements are important to observe and are much more easily detected if the patient raises his head from the couch, thus contracting the rectus abdominis while the needle is being inserted.

The original needle obtained from Switzerland is somewhat large; so the size has been reduced by the Genito-Urinary Manufacturing Co. Ltd., but the principle is exactly the same.

It is interesting to note that about 1925 G. Zorraquin, of Buenos Aires, designed a needle which was almost identical with this and was made by the Holborn Surgical Instrument Co. Ltd. for the exploration of the chest in cases of pleural effusion, so that fluid could be obtained without damaging the underlying lung.

Technical Minutiæ of Extended Myomectom Ovarian Cystectomy

VICTOR BONNEY, M.S., M.D., F.R.C.S., consulting
logical and obstetrical surgeon to the Middlesex
and consulting surgeon to Chelsea Hospital for
London : Cassell. Pp. 282. 30s.

THIS, the latest and probably the best book pen of Mr. Victor Bonney, is the gospel of the of conservatism. In it, with the utmost simp language and great clearness of detail, he almost every possible way of performing myomectomy. Mr. Bonney takes his reader and nary pupil by the hand and leads him into the and demonstrates each step in each type of op The 241 illustrations, drawn by himself, are in th style as those of the famous *Textbook of Gynæc Surgery*—little masterpieces of exposition. All logists and surgeons likely to perform myomectomy have this book.

The 1945 Year Book of Neurology, Psychiatry Endocrinology

Edited by HANS H. REESE and MABEL MASTEN; No
D. C. LEWIS; and ELMER L. SEVRINGHAUS. Chica
Year Book Publishers. Pp. 720. 18s.

SERVICEABLE and comprehensive, this triple vol devotes four-fifths of its space to neurology and crinology (almost equally divided) and a fifth psychiatry: clearly the editors consider that a proportion of the voluminous literature of psych adds nothing to our knowledge. It is conseq regrettable that space is allotted to reflective or exp articles, such as "viewpoints on basic proble psychopathology," "relationship of psychoanal psychiatry," "psychiatric problems in obstetri gynæcology," which contain little that is new. neurological section the editorial notes are frequ helpful; special attention is drawn to the me responses to intrathecal medication, and the adva of giving penicillin otherwise than by this route treatment of meningitis. The section on endocr is the last which Professor Sevringhaus will edit, prefatory note he compares the situation in 1931, he began the series, and now: great advances hav made, but fundamental relationships have not and there are still conspicuous gaps—for examp our detailed knowledge of the mechanism of the me cycle and of the hormones of the pituitary. This is, as ever, the most thickly packed, and bespeak great if uneven activity in this field that pre American laboratories and clinics, from which com of the papers abstracted. The value of the would be enhanced if the index were more itemis

A Practical Handbook of Midwifery and Gynæcol

(3rd ed.) W. F. T. HAULTAIN, M.B., F.R.C.O.G., obste
and gynæcologist to the Royal Infirmary, Edi
CLIFFORD KENNEDY, M.B., F.R.C.O.G., assistant
logist to the infirmary. Edinburgh: E. & S. Liv
Pp. 388. 20s.

THIS handy synopsis of obstetrics and gyn represents the teaching of the famous Edinburgh and it will therefore have a wide appeal north Tweed, but English readers will find the book acceptable to southern examiners. Though pr written for the student about to qualify, it is also book of reference for the busy practitioner who to check up on some point quickly. The chapters infant and on breast-feeding are particularly good the chapter on sexual disorders is useful and con small section on contraception. Not all will agree view that chloroform is the best anæsthetic when uterine relaxation is required for difficult rotati version, but the authors make the claim with laudable reservations. The Edinburgh school, sure, are masters in the administration of chloro but the English schools are not, and until its use is from obstetrics, some pregnant women will have lives endangered every year. There are other thetics available which are safer and equally efficient

THE LANCET

ONDON: SATURDAY, SEPT. 21, 1946

Occasion for Thrift

ι Armed Forces, it is clear, are to be maintained
ubstantial strength in peace-time ; but though
e claims must be met in peace as in war they
o longer have exclusive priority. Other tasks
nost equal urgency lie ahead : the country's
ged economy must be repaired, and the Govern-
has pledged itself to improve the life and lot
people. If these purposes are to be fulfilled
upply of skilled man-power must be carefully
nded and wisely allocated between the various
ants Thus the medical profession must meet
igher peace-time requirements of the Services
helping to man the new National Health Service,
will ultimately call for more doctors than the
ry now possesses. Plainly, more doctors must be
ed; the universities are alive to this fact,[1] but
cannot promise any large increase within the
few years. Meanwhile, the best use must be
of existing resources. In these straits, an
oritative body is needed to balance the claims of
an and military medical services and satisfy
that no doctor is wastefully engaged in either.
its establishment during the war, the Medical
onnel (Priority) Committee has concerned itself
exactly these questions. The committee's
ortance will be undiminished in the days of peace ;
ed, its brief should be extended and its member-
enlarged to represent all interested parties.
luties should, as now, be advisory, and, like other
ial committees that are in the making, it should
ish its findings

nere will be plenty of work for the committee.
night first consider the proposal that medical
ents shall continue to be called up for military
ice, except when specially deferred, before starting
r medical course proper. The alternative system,
which doctors would normally do their military
ning after qualifying, would require close under-
ding between the Ministries of Labour, Education,
Health, and the universities and Service depart-
ts ; and it could not be effected immediately since
medical schools already have more candidates
they can accept from the ranks of the demobilised
in a year or two the change should be practicable,
it is not too early to plan for that time Many
lents would prefer that the break, if break there
t be, should come between school and university
ier than later ; but will it not be more profitable
both the community and the individual if the
tor serves after qualifying, when he can help to
ice Service demands on the country's restricted
ply of medical men and can gain the knowledge of
rice medicine which he will need if ever he is
lled to the Forces ?

hen there is the step which many think inevitable
ie merging of the medical branches of the three Fighting Services into a single organisation, no longer keeping itself aloof from civilian medicine but closely linked to the National Health Service. This measure would provide doctors in the Forces with an opportunity for widening their experience and might well increase the efficiency of medical care for all fighting men ; but above all would be its saving in overlap and hence the economy it would effect in hospitals, equipment, and man-power. This step was advocated early in the war by MEDICUS, M.P.,[2] after a tour of the B.E.F., and now, as then, the need is for a unifying authority. The Personnel Committee would be well constituted to study this scheme in detail and to advise on its practicability.

There is a further aspect of economy that should not be overlooked : time spent with the Forces should be profitably occupied. And here again is an opportunity for the integration of military and civilian medicine which we have already discussed in detail.[3] The late war proved the eagerness of the young medical officer, even under difficult conditions, to enlarge his experience. This thirst for further knowledge was to some extent recognised and appeased by short courses and clinical meetings in hospitals ; during the last campaign in Europe one hospital (known, with a levity that concealed respect, as the University of Duffel) won a reputation for teaching that might be the envy of established centres. In peace-time this field can be more fully explored (see p. 432). It may be found that some of the best teachers have returned to civilian life, and certainly much will depend on the good will of civilian hospitals. The Services, for their part, may look with favour on a suggestion which is calculated to increase their appeal and efficiency. The newly recruited medical officer must first serve with a battalion or in a comparable post with the other Services, for this work calls for a special knack that is not learnt overnight. Moreover, better than any other appointment, it teaches the precise functions and effects of Service medical practice ; indeed, many of those who joined the Forces for the duration as specialists suffered a permanent disability through not having held these posts But training should also include opportunities to work in military medical units, large and small, and even in administrative offices. This arrangement would not only benefit the Services by instructing men in their operation but might also, by providing first-hand experience of many branches of medicine, enable junior graduates to return to civilian life with a better idea of where their bent lay.

Service with the Forces should not be divorced from, or delay advancement in, civilian work, but should rather be a normal phase in a single career. It may be that in the years to come the young doctor will be able to count his time in the Forces towards seniority in the National Health Service, and that senior men will be free to return to the Services for short periods without jeopardising their civilian position ; they might, if specialists, thus help to make good a deficit that will probably be felt even more strongly in the Services than in civilian practice. Such a correlation may have to wait on more settled days ; but economy in the use of doctors cannot wait.

3 water-soluble vitamins in one tablet

● Stomatitis, anorexia, gastro-intestinal disturbances, states of debility, fatigue, and certain skin disorders are often associated with a lack of the water-soluble vitamins, nicotinic acid, B_1 and C. When these vitamins are supplied as an adjunct to treatment an improvement is usually noted. 'Nicorbin' tablets containing these nutrients, given thrice daily, supply the average adult requirement.

During pregnancy and lactation, and during the process of wound healing the increased demands for these vitamins are met by supplying 'Nicorbin.' Whenever, from deficient dietetic intake or excessive physiological need, these water soluble vitamins are required, 'Nicorbin' will prove valuable.

COMPOSITION

Each 'Nicorbin' Tablet contains —
Aneurine Hydrochloride (vitamin B_1) 1 mg
Ascorbic Acid (vitamin C) 25 mg.
Nicotinic Acid (P.P. factor) 10 mg

PRODUCT OF THE GLAXO LABORATORIES

NICORBIN

GLAXO LABORATORIES LTD., GREENFORD, MIDDLESEX. BYRon 3434

roups, and TANNER has seen it even at 91; it s certain that this diagnosis is often overlooked. he old patient with ulcer, gastrojejunostomy is ient, for the mucosa is usually degenerative and ation does not recur. The stomach growth, of se, does require partial gastrectomy, and it is zing how well the aged withstand this procedure. NER records a successful total gastrectomy in a ent of 74, and WAUGH and GIFFIN[9] one in a ent of 72. In such patients preliminary splanchnic k may be dangerous, for, especially with the rior approach, pressure on the aorta may fracture e of the atheromatous plaques usually present. ection of œsophageal growths is now being success- performed even in old patients, and the risks are h taking. The pharyngeal pouch quite common ne aged is being dealt with under local anæsthesia irst transplanting the pouch to a higher level and second operation coring out the mucosa. Growths ne colon can be expeditiously dealt with by Paul's ation, and even if there are secondaries in the an attempt should be made to remove the local rth. Patients with secondaries in the liver often for two or three years in fair comfort and removal spare them the misery and pain of the local ad. The aged do not always need the full abdomino- ineal resection; where the growth is at the irectal junction, or high in the rectum, the simpler ration of leaving a distal blind rectal stump rtman's operation) is ample. CUTHBERT DUKES,[10] GLOVER and WAUGH[11] have shown that distal ograde spread is slow, and that it only occurs in of cases, and then usually only when the normal vard channels have been blocked. Section of the vel an inch below the palpable edge of the lesion satisfy pathological requirements. The breast cinoma usually needs but a local amputation to oid the local ulcerating mass, and to remove what patient knows perfectly well is slowly whittling ay her life. Admittedly, such carcinomas are often remely slow growing, but, with the ever-extending opaganda on cancer of the breast, no patient can miss it lightly from her mind. Minor operations, n circumcisions, are often necessary in old people d should not be shirked. Hæmorrhoidectomy can ily be performed under local anæsthesia. The frail lady withstands well an operation for procidentia, d it will give her comfort. As HOWELL astutely narks, "trifling matters often distress the aged ore than great ones."

The possibility of a vascular catastrophe alway vers over the old patient. Embolism of a mesenteric peripheral vessel is a condition amenable to gery, and has to be borne in mind. The peripheral bolus is too often overlooked till too late for gery: numbness and loss of power, rather than in, may be the chief symptoms. The limb with a ripheral embolus, if operated on early (usually under al anæsthesia), does well. Arteriosclerotic gangrene now being treated by more conservative methods; ngrene of a single toe often ends with no more than s of the superficial skin. Reflex vasodilatation,[12] heating the body or immersing the opposite limb in water at 110° F, is probably the best way of encouraging the collateral circulation; it does as much as a sympathectomy and certainly more than vasodilator drugs. For the frail patient, particularly with spreading gangrene, amputation under ice anæsthesia has a place. The results of surgery in the "old man's illness"—prostatic obstruction—have been much improved; Millin's retropubic operation has largely justified the original optimism. The other old person's disease, trigeminal neuralgia, is being increasingly operated on early, and these patients withstand the operation remarkably well. Fractured neck of femur, which was the harbinger of death for many of the aged in the past, is now almost routinely treated with the trifin nail—a procedure which even the very old withstand well. Aseptic necrosis and extrusion of the pin have rather damped initial hopes, but a good result can usually be anticipated in at least 50% of cases; where this fails McMurray's osteotomy is extremely valuable.

One example of the success being attained must suffice. CARP[13] has collected figures from a variety of sources covering 2558 patients submitted to operation at ages over 60; these show an average operative mortality of 13·1%—a gratifying result. It does indeed seem that the age of the "lean and slippered pantaloon" may become a less formidable problem to the surgeon than that of the "fair round belly with good capon lined."

Annotations

DENTAL CONTROVERSY

THE dispute between the dental profession and the Minister of National Insurance raises an important point of principle. Negotiations for a new scale of fees for dental work done for insured persons began as long ago as January of this year, when the Dental Benefit Council set up a negotiating committee consisting of three dentists, representatives of three approved societies, and a number of Government members. This committee issued a questionary to more than 1000 dentists engaged in N.H.I. practice to ascertain (*a*) to what extent the cost of running a practice had risen owing to the war, and (*b*) what were the private fees charged to non-insured patients in the same walk of life as those treated under N.H.I. The committee issued a unanimous report and submitted a scale of fees which represented an average increase of about 100% over the pre-war scale. This scale of fees has now been rejected by the Minister of National Insurance. The dental profession feels that having exhausted what it regards as the normal negotiating machinery it has no alternative but to abstain from participating in the service. The dental profession fears that if the present Minister is prepared to disregard negotiating machinery in connexion with dental benefit in this way, and to rate the value of a dentist's services so low, there can be no hope of any better treatment in a scheme applying to the whole nation.

The scale which the Minister proposes to adopt from Sept. 30 will yield an average net increase of 50% over pre-war, according to the Ministry's letter circulated to dentists on Sept. 12, but the rise is not uniform. Thus the fee for full upper and lower dentures, which unfortunately is the form of treatment most necessary for working-class patients, is £7 15s. When the scheme started in 1926 this fee was £6; the present fee is £6 7s. 6d.; and the dentists were prepared to accept 9 guineas. The dentists contend that they cannot

Surgery in the Aged

THE defeatism to surgical diseases in the aged is passing. The view of operation on the elderly as a desperate expedient is still reflected in the undue proportion of old people with acute surgical complaints to be found in institutions for the chronic sick; but the E.M.S., by sending doctors from voluntary hospitals as emergency staff to these institutions up and down the country, has influenced surgical opinion on the illnesses of old people. Many surgeons have returned to voluntary hospitals with an increased respect for the tolerance of the elderly for major operative procedures. The improved expectation of life means inevitably that surgeons will be increasingly occupied with patients over 60.

As TANNER[1] remarks, the improved results are not so much due to changes in technique as to better pre- and post-operative care and a higher standard of anæsthesia. The old patient's knowledge of dietetics is rarely profound; he is often faddy, practising self-imposed restrictions, especially on protein foods, green vegetables, and fruit. Rationing difficulties and poverty have usually added their burden. A preliminary period in hospital before operation, when surgical circumstances permit, is well spent; WHIPPLE[2] has pointed out the need for extra proteins to increase the powers of wound healing, and STEVENSON, WHITTAKER, and KARK[3] have found powdered milk useful for this purpose. With syrup flavourings it can be made into a palatable drink, and should be given between meals, say at 10 A.M. and 2.30 P.M., in 8 oz. feeds, and a further 16 oz. as a milk-shake at 9 P.M. By this means 72 g. of protein and 1100 calories can be added to the daily diet. It seems unnecessary to give amino-acids. Extra vitamin C is needed for the formation of collagen fibres,[4] and many of these old patients bear the stigmata of vitamin-B deficiency; so vitamin supplements in full doses should be added to the diet. The hæmoglobin needs watching, for many of these old people are anæmic; this is best corrected with iron, or if need be liver, for blood-transfusion requires particular care, since their hearts will not tolerate much overloading. Bed is a dangerous place for the old man; as often as not rest in bed, rather than the surgeon, is responsible for a pulmonary embolus. This is a complication ever to be feared in the aged, and in some operations a preliminary double femoral ligation, as is being increasingly practised in America, might be advisable. Just before operation is not the best time to change the habits of a life-time, so enemas and purges are better avoided. Smoking should be restricted for 48 hours before operation, but it will do no good to cut off the pipe after meals and have the patient fumbling, restless, and miserable. Morphine, when indicated for pain, should be given in small doses. HARDY, WOLFF, and GOODELL[5] have shown that the maximum analgesic effect is obtained with gr. $^1/_6$, and that a larger dose merely depresses respiration The patient who requires preoperative gastric lavage should have his washout first thing in the morning and just before the evening meal; the usual practice of leaving the empty for the night robs the patient of the of the night's absorption of food and fluid

Of all the anæsthetics for the aged, local with the patient preferably asleep (at any rate Englishman), seems to be the most spinal anæsthetics, especially high spinals, are tolerated by old people. Gas and oxygen is the most dangerous, for any sustained cyano lethal. Light cyclopropane is almost certain safest. The old patient should not be intubated routine; when the patient is light this leads to bronchial spasm, and, as NOSWORTHY[6] has out, this may largely be responsible for lung collapse. Postoperatively, intravenous d better avoided; with a small catheter at least 5 of fluid a day can be administered by rectal Protracted gastric aspiration is badly tolerated, it is often maintained unnecessarily long after abdominal operations. Although his tissues heal well, an the peritoneal cavity does not seem to lose its po of coping with any mild spilling, the old per resistance to infection is always poor, penicill preferably started before operation, is a valu weapon against wound sepsis, which may spread i the peritoneal cavity and be responsible for the su quent peritonitis. To avoid the unpleasantne repeated injections, penicillin may now be g in 100,000-unit doses, and Dr. FLOREY and colleagues demonstrate in this issue (p. 405) that dose given thrice daily will maintain a bacterio concentration in the blood. Prophylactic sulphona therapy TANNER thinks is of definite value ag pulmonary and peritoneal infection; he quo series of 120 unselected partial gastrectomies w one death, and attributes part of this succe sulphonamides. Sulphamerazine may come to the drug of choice, for it has the advantage of requ only 8-hourly administration and its conjugated f is relatively soluble in neutral and acid urine, t avoiding the risks of drug concretions and da to the renal parenchyma.[7] Succinyl sulphathi has proved its value in the preoperative prepar of the patient for intestinal surgery; in append so treacherous in the aged, it may be used as an ad safety factor. For diverticulitis, often seen in aged, phthalyl sulphathiazole, which requires daily dose of 3–6 g., may be superior.

In the decision to operate on an old pers surgeon should not be too much influenced b knowledge that the patient's blood-pressure is even a history of coronary thrombosis is no ab contra-indication. Hypertension was present in of 341 "healthy" Chelsea pensioners examined HOWELL.[8] "Give me preferably the old patient high blood-pressure," GORDON-TAYLOR has remar Fall of pressure in the aged is a bad prognostic and when "systolic figures approach 110, the out is grave."[8] The surgeon should bear in mind hæmoptysis, hæmatemesis, and profuse rectal blee may result from hypertension rather than disease. Gastric surgery for ulceration is now increasingly performed with success in old p Gastric perforation is by no means rare in the

TEST FOR THREATENED ABORTION

presence of pregnandiol in the urine can be deter- qualitatively by a colour reaction which is neither ularly involved nor time-consuming; and Guter- now claims that this can be used as a diagnostic r pregnancy with an accuracy comparable to that Friedman test. He suggests, moreover, that the on is an accurate aid to prognosis in certain ications of pregnancy, notably threatened abortion. gnandiol is the excretion product of progesterone, appears in the latter half of the cycle, ceasing one ur days before the onset of menstruation. If sation occurs the corpus luteum persists and the ion of pregnandiol continues. In normal pregnancy cretion of pregnandiol follows a fairly well-defined m. At first it is comparable to that in the latter f a normal menstrual cycle, but about the ninth elfth week the excretion rises sharply to reach a two weeks before delivery; it then drops sharply, regnandiol has completely disappeared from the twenty-four to forty-eight hours after delivery. well known clinically that the corpus luteum begins generate about the third month of pregnancy, which double oöphorectomy can be carried out ut necessarily disturbing the pregnancy. It is ble that the placenta assumes the function of ing progesterone from about the twelfth week rds; and the commonest time for abortion corre- ls to the stage at which the corpus luteum is sing and the placenta is beginning to take over nction. During this transitional period pregnandiol tion is liable to drop to a low level; and a drop the danger zone may well herald the onset of tened abortion. The test could thus forewarn the ian, who could take evasive action by ordering sedative drugs, and possibly progesterone by ion.

terman's colour reaction[2] consists briefly in adding ntrated sulphuric acid to the pregnandiol extracted the urine; a positive reading is indicated by a deep r or orange, which represents 0·4 mg. pregnandiol 0 c.cm. of urine, or roughly 6–10 mg. in twenty-four —the normal amount in early pregnancy. He d 73 patients with threatened abortion; among the pregnandiol colour reaction with concentrated uric acid was persistently negative in 39, of whom orted. The reaction was persistently positive in whom 30 did not abort. Out of the 73 there were ng prognoses; but in 3 of the 4 positives that ed there was good reason for it—placenta prævia o and a large fibroid in the third. The test is most up to the third month. Thereafter with the tion of pregnandiol rising from 20 mg. to 50 mg., a positive reading may persist for the first twenty- hours after fœtal death. Guterman offers no explanation of the pregnancy which continues despite a persistently negative colour reaction. The great advantage of the method is its cheapness and speed; a result can be obtained on the day that the specimen reaches the laboratory. It is hoped that English workers will try it out; if it is found to be as good as Guterman claims, it should prove useful in the treatment and prognosis of threatened abortion.

HOSPITAL CATERING IN MIDDLESEX

By way of experiment, the Middlesex County Council have decided to appoint a catering officer to one of their hospitals.[1] The appointment is in the first instance to be temporary, though not with any fixed limit of time, and is to carry a salary of £750 a year, rising by annual increments of £25 to £850. In a report to the public-health committee, Dr. H. M. C. Macaulay, county medical officer of health, notes that existing arrangements present many of the drawbacks discussed by King Edward's Hospital Fund for London.[2] Thus hospital catering comes under the dual control of the steward, who undertakes the buying and supervises the porters who distribute the food to the wards, and the matron, who supervises both the kitchen staff and the nurses. The matron may have the help of a housekeeping sister, whose short course of training, planned in days when hospitals were smaller, is mainly administrative, does not include cooking, and seldom covers nutrition or the relation of food to health.

Dr. Macaulay found the matrons ready enough to be relieved of the responsibility of catering; but the stewards, though agreeing that it should be under one person, were uneasy over the proposed appointment of a catering officer. They feared the results of divided control of staff, especially porters, and of stores, since food would have to be separated from other goods: and they concluded that the person responsible for catering should either be the steward or else that the catering officer should work under him.

It is doubtful whether this is the right arrangement. As the King's Fund point out, stewards have little expert knowledge of food, cooking, and the science of nutrition, and their general administrative duties do not leave them time to visit markets and interview travellers. They have to depend on the long-term contract, the written order, and the telephone in buying food; Dr. Macaulay, in fact, noted that the contract purchase was much too common. Yet a day-to-day first-hand knowledge of markets is needed for clever buying of seasonal foods, and a balanced diet can only be provided by a man or woman who understands nutrition and is free to juggle with the commodities at his disposal. Much, of course, must depend on the quality of the caterer appointed; experienced caterers are scarce, and until more have been found or trained it may be well to go cautiously. In deciding to appoint one catering manager, Middlesex County Council leave themselves free to experiment with stores arrangements and in other directions.

In addition, food service subcommittees are to be appointed in all the council's hospitals, made up of the medical director, members of the medical staff, and the officers responsible for hospital feeding, including the matron, and the dietitian and caterer where these exist. These committees will be able to reconcile the financial, medical, nursing, dietetic, and administrative interests concerned, and to deal with complaints about food. It will be interesting to see whether they develop on the lines set out by the King's Fund, as technical and

guarantee a satisfactory service for insured persons at any scale below that which the Minister rejected, and the Joint Advisory Dental Council recommends dentists to refuse to undertake N.H.I. work unless the higher scale is adopted.

PERCEPTION

THERE are many subjects of common interest to philosophy and medicine: but if he is a physician the Manson lecturer, required by the terms of his appointment to consider some such subject, may well doubt his ability to reach the standard of subtle and recondite profundity manifest in philosophical writings. Dr. Russell Brain[1] has, however, succeeded in illuminating a problem of basic importance for the philosopher—the nature of perception, especially in its causal aspects. Neurologists, he points out, usually adopt physiological idealism as their epistemological theory: for them the only independently necessary condition for the awareness of sense-data is an event in the cerebral cortex. But, besides the familiar arguments against idealism, it is possible to object to this, as Russell Brain does, that the peculiar phenomena of cortical representation during visual perception make simple "projection" of cerebral events an inadequate explanation: "when we perceive a two-dimensional circle we do so by means of an activity in the brain which is halved, reduplicated, transposed, inverted, distorted and three-dimensional." But realism too has its difficulties, implicit in Brain's (probably rhetorical) hope that a realist philosopher will give an account of the "ontological status of a black sense-datum when it is not being perceived and, in particular, its relationship to its non-existent substratum in the physical world."

By way of hallucinations and the phenomenon of "phantom limb," which further illustrate this crux, Brain passes to the rôle of the body in perception, and instances a number of observations hard to reconcile with any variety of critical realism. Awareness of externality is clearly the cardinal problem: and spatial relations, upon which this depends, are primarily perceived in a somatocentric way. The body is well adapted to the task of spatial discrimination, through its apparatus for the integration of impulses conveyed from different sense-organs to the cerebral cortex. Russell Brain holds that the most likely explanation of the relationship between sense-data and the nervous system is that a sense-datum is a neural event which is conducted from the surface of the body to the surface of the brain but which carries with it some characteristic of the physical stimulus which excited it. In his conclusion, which takes account of the "successiveness" of the stimulus event, he adopts a realist position in so far as he denies that even secondary qualities are generated by our brains or minds: "in sensing them we are perceiving the four-dimensional texture of the external world." This is a thoughtful and stimulating essay which shows how significant for the philosopher can be the observations and reflections of the neurologist.

DEATH AFTER CURARE

AN inquest was held at Hammersmith on Sept. 9 on a patient who died after an operation in which curare was employed. A woman of 70 years had been admitted to hospital two days after the onset of symptoms of acute appendicitis. An hour after receiving morphine gr. $^1/_6$ and atropine gr. $^1/_{100}$, she was anæsthetised with 'Pentothal' 1 g. and was given 'Intocostrin' 9 c.cm. Oxygen was administered during the operation, which revealed an acutely inflamed but unruptured appendix, with much induration of the surrounding tissues and a small adjacent collection of pus. The appendix was removed, the pus mopped out, and the wound closed in layers. The first alarming signs—cyanosis and shallow respiration—appeared after the end of the operation, which had taken 43 minutes. The patient recovered somewhat with oxygen and carbon dioxide, but relapsed and, despite the injection of 'Coramine' 1 c.cm. and 'Veritol' 1 c.cm., died 35 minutes later. Necropsy confirmed the presence of early peritonitis, which was most pronounced in the right iliac fossa; there was some dilatation of the terminal loops of the ileum, suggesting early paralytic ileus. The left lung was almost completely collapsed and there was considerable collapse of the posterior halves of the right upper and lower lobes; there were one or two adhesions in both pleural cavities and the lungs showed pronounced terminal congestion. The heart muscle was a little friable, but only early atheromatous changes were found, and there was no valvular disease. Early toxic changes were seen in the spleen and liver. The kidneys were remarkably healthy for a patient of this age, although albumin had been found in the urine before operation. The pathologist considered that death was due to toxæmia and had been accelerated by respiratory failure due to curare. A verdict of death by misadventure was returned.

PENICILLIN IN WOUNDS

THE topical application of sulphonamides to wounds has proved a disappointment, and, though there is not unanimous opinion on this point, it is widely held that the presence of a sulphonamide powder in a flesh wound may actually delay healing. In sharp contrast to this, there has never been a doubt that penicillin as a topical application is of great value, for it has the advantages over the sulphonamides that it acts in the presence of pus, that its effect is not weakened by large numbers of bacteria, that it is a much more powerful bacteriostatic agent than any sulphonamide, and that it is very soluble in tissue fluids. In the early stages of its use, penicillin was recommended as a topical application because this method was more economical than systemic administration at a time when supplies were short; and many surgeons believed that, valuable as it was used thus, its effects would be greater still when easement in the supply position permitted free systemic administration. This belief has not been borne out in practice, and the paper by Florey, Turton, and Duthie in this issue gives scientific foundation for the clinical impression that locally applied penicillin is as effective in preventing wound infection as it is when given parenterally.

Florey and her colleagues collected samples of wound exudates after penicillin had been given either by local application or by injection. The difficulties they encountered in the assay of the penicillin content of these exudates and the methods they used to overcome them need not detain us here. It was shown that whereas 100,000 units of penicillin injected intramuscularly yielded for a minimum of 8 hours a wound exudate which inhibited the test organism, a similar dose implanted in the wound yielded exudates with inhibitory concentrations for at least 48 hours. It might be argued from this observation that locally implanted penicillin remained in the wound cavity but might fail to reach organisms lying in the wall, but this argument is defeated by observations on the duration of inhibitory activity in the blood and urine. There was little difference in the time over which inhibitory levels were maintained in the blood whether penicillin was given locally or parenterally, but in the urine inhibition persisted in half the cases for twice as long after local application as it did after intramuscular injection. Penicillin is therefore readily absorbed from wounds and must traverse the walls of wounds (inhibiting meanwhile organisms lying in its path) to gain access to the blood and urine.

All this is of great importance in its practical application to wound treatment. Locally implanted penicillin is of greater value, unit for unit, than injected penicillin in the control of wound infection—a conclusion which all patients will welcome if it means that the 3-hourly injection régime can be avoided. It is clear, also, that so far we have not put nearly enough penicillin into the unds we have treated and have therefore had to waste by supplementary systemic administration. Some ctical points await elucidation. Can one put into a und a large enough dose of penicillin to sterilise it h certainty at a single stroke? Do the tissues show arked resentment to pure powdered penicillin in quan- , and would healing be impeded by excessive exuda- n? If a single sterilising dose proves impracticable, at is the best method of implanting penicillin into a ured wound at, for-example, 24-hourly intervals? seems that despite the vast experience of the past six ars, the last word on the best method of treating unds with penicillin has yet to be said.

TEST FOR THREATENED ABORTION

THE presence of pregnandiol in the urine can be deter- ined qualitatively by a colour reaction which is neither rticularly involved nor time-consuming; and Guter- an[1] now claims that this can be used as a diagnostic st for pregnancy with an accuracy comparable to that the Friedman test. He suggests, moreover, that the action is an accurate aid to prognosis in certain mplications of pregnancy, notably threatened abortion. Pregnandiol is the excretion product of progesterone, d it appears in the latter half of the cycle, ceasing one four days before the onset of menstruation. If rtilisation occurs the corpus luteum persists and the xcretion of pregnandiol continues. In normal pregnancy he excretion of pregnandiol follows a fairly well-defined attern. At first it is comparable to that in the latter alf of a normal menstrual cycle, but about the ninth o twelfth week the excretion rises sharply to reach a eak two weeks before delivery; it then drops sharply, nd pregnandiol has completely disappeared from the rine twenty-four to forty-eight hours after delivery. t is well known clinically that the corpus luteum begins o degenerate about the third month of pregnancy, fter which double oophorectomy can be carried out without necessarily disturbing the pregnancy. It is robable that the placenta assumes the function of ecreting progesterone from about the twelfth week nwards; and the commonest time for abortion corre- sponds to the stage at which the corpus luteum is regressing and the placenta is beginning to take over its function. During this transitional period pregnandiol excretion is liable to drop to a low level; and a drop into the danger zone may well herald the onset of threatened abortion. The test could thus forewarn the clinician, who could take evasive action by ordering rest, sedative drugs, and possibly progesterone by injection.

Guterman's colour reaction[2] consists briefly in adding concentrated sulphuric acid to the pregnandiol extracted from the urine; a positive reading is indicated by a deep yellow or orange, which represents 0 4 mg. pregnandiol per 100 c.cm. of urine, or roughly 6–10 mg. in twenty-four hours—the normal amount in early pregnancy. He studied 73 patients with threatened abortion; among these the pregnandiol colour reaction with concentrated sulphuric acid was persistently negative in 39, of whom 38 aborted. The reaction was persistently positive in 34, of whom 30 did not abort. Out of the 73 there were 5 wrong prognoses; but in 3 of the 4 positives that aborted there was good reason for it—placenta prævia in two and a large fibroid in the third. The test is most useful up to the third month. Thereafter with the excretion of pregnandiol rising from 20 mg. to 50 mg., a positive reading may persist for the first twenty-[illegible] hours after fœtal death. Guterman offers no explanation of the pregnancy which continues despite a persistently negative colour reaction. The great advantage of the method is its cheapness and speed; a result can be obtained on the day that the specimen reaches the laboratory. It is hoped that English workers will try it out; if it is found to be as good as Guterman claims, it should prove useful in the treatment and prognosis of threatened abortion.

HOSPITAL CATERING IN MIDDLESEX

BY way of experiment, the Middlesex County Council have decided to appoint a catering officer to one of their hospitals.[1] The appointment is in the first instance to be temporary, though not with any fixed limit of time, and is to carry a salary of £750 a year, rising by annual increments of £25 to £850. In a report to the public-health committee, Dr. H. M. C. Macaulay, county medical officer of health, notes that existing arrangements present many of the drawbacks discussed by King Edward's Hospital Fund for London.[2] Thus hospital catering comes under the dual control of the steward, who undertakes the buying and supervises the porters who distribute the food to the wards, and the matron, who supervises both the kitchen staff and the nurses. The matron may have the help of a housekeeping sister, whose short course of training, planned in days when hospitals were smaller, is mainly administrative, does not include cooking, and seldom covers nutrition or the relation of food to health.

Dr. Macaulay found the matrons ready enough to be relieved of the responsibility of catering; but the stewards, though agreeing that it should be under one person, were uneasy over the proposed appointment of a catering officer. They feared the results of divided control of staff, especially porters, and of stores, since food would have to be separated from other goods; and they concluded that the person responsible for catering should either be the steward or else that the catering officer should work under him.

It is doubtful whether this is the right arrangement. As the King's Fund point out, stewards have little expert knowledge of food, cooking, and the science of nutrition, and their general administrative duties do not leave them time to visit markets and interview travellers. They have to depend on the long-term contract, the written order, and the telephone in buying food; Dr. Macaulay, in fact, noted that the contract purchase was much too common. Yet a day-to-day first-hand knowledge of markets is needed for clever buying of seasonal foods, and a balanced diet can only be provided by a man or woman who understands nutrition and is free to juggle with the commodities at his disposal. Much, of course, must depend on the quality of the caterer appointed; experienced caterers are scarce, and until more have been found or trained it may be well to go cautiously. In deciding to appoint one catering manager, Middlesex County Council leave themselves free to experiment with stores arrangements and in other directions.

In addition, food service subcommittees are to be appointed in all the council's hospitals, made up of the medical director, members of the medical staff, and the officers responsible for hospital feeding, including the matron, and the dietitian and caterer where these exist. These committees will be able to reconcile the financial, medical, nursing, dietetic, and administrative interests concerned, and to deal with complaints about food. It will be interesting to see whether they develop on the lines set out by the King's Fund, as technical and professional committees, analogous to hospital medical committees, advising their hospital boards, and regularly consulted by them before any decisions are made to reduce expenditure on kitchen staff or provisions. Economics of these kinds can be expensive, whereas increases in kitchen salaries have on occasion been more than counterbalanced by savings on waste. The classic example is that published by the King's Fund in 1943 of a hospital which raised the total wages of kitchen staff from £1000 to £2000, and enjoyed a fall in the total costs of catering from £20,000 to £14,000.

TESTOSTERONE AND ANGINA PECTORIS

MEDICAL propaganda is not without its risks, especially in the hands of an enterprising journalist. Testosterone for angina pectoris is an example of a comparatively untried treatment which has been prematurely popularised in this way. In the U.S.A. many people with angina are said to be either treating themselves with the drug or urging their doctors to prescribe it. That its worth is as yet unproved is confirmed by the latest report from America. Levine and Sellers [1] gave 25 mg. of testosterone propionate intramuscularly twice or thrice a week and 10–15 mg. of methyl testosterone sublingually every day to 21 men with angina pectoris; 11 showed no improvement and only 2 showed "marked improvement." Of the 10 patients who had male climacteric symptoms (precordial discomfort) in addition to angina pectoris 6 reported that these symptoms were much improved. Other workers [2] have reported similar results—failure to relieve angina pectoris, but relief of chest symptoms attributed to the so-called male climacteric. There seems to be good reason for the conclusion of Riseman [3] that testosterone should be classed among agents of no value in angina pectoris.

SILICOSIS AND ALUMINIUM TREATMENT

LAST year we drew attention [4] to the patenting by Canadian investigators of the aluminium treatment for silicosis. It now appears that the patent does not apply to Great Britain and that research-workers in this country are free to experiment with the method. The subject has been considered by the councils on industrial health and on pharmacy and chemistry of the American Medical Association which in April issued the following report [5]:

1. In experimental animals the *prophylactic* use of aluminium inhibits the toxic action of relatively pure quartz.
2. In man, industrial dust exposures often involve mixtures of various minerals in addition to quartz and other environmental variables to which experimental animals are not subject. Therefore human silicosis usually develops more slowly and is often modified in type. Only prolonged unbiased observation, with adequate control cases, will demonstrate whether the prophylactic results obtained with animals are applicable to man.
3. Animal experiments have demonstrated that administration of high concentrations of amorphous hydrated alumina unfavourably influences resistance to tuberculosis. While this result has not yet been reported for metallic aluminium, caution in the application of all aluminium therapy to human beings is recommended.
4. The use of aluminium might appear as an easy short-cut to healthful working conditions, thus saving large expenditures for ventilation and other control methods. Actually there is no substitute for the accepted methods of dust control.
5. If industry indiscriminately treats all employees with aluminium dust there may be aggravation of tuberculosis or other pulmonary conditions.
6. The *therapeutic* use of aluminium in man appears to relieve symptoms in a very small number of cases in which silicosis develops rapidly. Experience in some groups is more favourable than in others.
7. In view of these considerations it is recommended that the general application of aluminium therapy in industry be delayed until adequately and impartially controlled clinical observation demonstrates its effectiveness in preventing or alleviating silicosis in man. In the meantime, there should be no slackening in the control measures that have been found effective in reducing the incidence of dust diseases in industry.

We agree heartily with this opinion and repeat that the "results of treatment and prevention of silicosis by the aluminium method, while suggestive, are not yet convincing, and much more work by independent and untrammelled observers is needed to establish its efficacy." We hope too that the freedom of this country from the effects of the Canadian patent will not result in the indiscriminate establishment of aluminium inhalation chambers at factories or other places where there is risk of silicosis. The only established method of preventing the disease is by seeing that workers *do not breathe* the dust of free silica.

FATE OF THE NERVE HOMOGRAFT

TRIALS by Seddon and Holmes [1] of nerve homografts for bridging gaps in injured peripheral nerves indicate that, despite its success in cats, rabbits, and monkeys,[2] the method is ineffective in man. Barnes and his colleagues [3] have also made a careful investigation of homografts in 8 cases of peripheral-nerve injury where the gap between the divided ends of the nerve could not be bridged by any other method; in no case was there any recovery of neural function. At varying intervals after insertion, when it was apparent that no recovery was occurring, the wound was explored and the graft inspected. In 3 cases the graft was removed and studied histologically 140, 355, and 904 days after insertion. In all 3 cases regenerating nerve-fibres crossed the suture line and penetrated the graft for varying distances, the greatest being 25 mm. In the graft there was necrosis of the fascicles and some fibrous replacement, the extent of which appeared to depend on the time that the graft had been in place; in the third case, examined at 904 days after insertion, there was dense fibrous tissue and no evidence of the original graft elements.

Barnes and colleagues point out that the reaction to a homograft differs fundamentally from the reaction to an autograft. The fibrous replacement of a homograft appears to be due to a reaction of the host's tissues; with an autograft the architectural characteristics of the graft are maintained, and fibrosis results from the proliferation of its connective-tissue elements. Why a homograft undergoes necrosis and fibrous replacement is still uncertain; Barnes and colleagues suggest that it is the result of "active acquired immunity"—a view originally expressed by Gibson and Medawar [4] in relation to skin homografts. Seddon and Holmes think that where the gap is short, as in the rabbit, the tissue reaction may not occur until outgrowing fibres have reached the peripheral stump, and that in man, where the gap may be long, the immune reaction attains its greatest intensity long before the fibres have had time to traverse the gap.

Until more is known about the mechanism and control of the host's acquired immunity, the nerve homograft will find no place in the surgery of peripheral-nerve injuries.

Reconstruction

HEALTH EDUCATION

ITS PROBLEMS AND METHODS *

WALTER P. KENNEDY
Ph.D. Edin., L.R.C.P.E., F.R.S.E.
MEDICAL OFFICER, MINISTRY OF HEALTH

HEALTH education is a comparatively new subject. t has not yet been formulated in doctrine and pedagogic methods, as has been done with the older disciplines, uch as botany and chemistry. To say this is not to isregard the work of those devoted medical men and dministrators, such as Heberden, Fothergill, Smellie, Snow, and Chadwick and Simon, who laid the basis of scientific hygiene and gave it practical expression in public-health legislation.

The labours of the early hygienists involved convincing the public so completely that their discoveries were correct that the result was a general demand for egislative action and an acceptance of the laws when they were made. This meant instruction in the requirements for health, and it is the democratic method. But a glance at the history of preventive medicine or hygiene in modern times is enough to show us the main grounds for the claim that health education is a new subject.

The preoccupation of hygiene is with the prevention of disease—and very properly so—while the preoccupation of the new health education is with the promotion of health. The difference is that between a negative and a positive point of view. It is true that health education could not have developed as an idea without the prior creation of a firm foundation of preventive medicine, but it is an extension from the older concepts of the hygienists and sanitarians, and it has its separate contribution to make to national welfare.

The time seems ripe to attempt at least an elementary analysis of the general concept and to formulate principles for its further development. The following views are presented as no more than a hypothesis upon which a thesis may later be made. They are far from complete, but their purpose will be accomplished if they only act as catalysts to stimulate discussion among other workers in the field.

DEFINITION

It is of first importance in any discussion to be definite about the meaning of the terms used ; so we must make a semantic examination of the word " health." This is not easy, for health is a state of being and, as a biological phenomenon, is in a continual condition of flux. Some time ago I looked up the definition of health in all the dictionaries and textbooks at hand, and could not find a single definition which satisfied the criteria laid down in formal logic. For example, to say that health is "wholeness or soundness of body and mind" does not really take one any further. At last it appeared that the method of classical logic was inadequate to supply the required answer. It was necessary to apply the logic of the continuum as, for example, used by Bogoslovsky.

For the purposes of this dynamic logic we will postulate that we can only consider health by also considering its opposite, disease. This pair of contrasting concepts may be regarded as opposite poles joined by a line along which we can measure the distance of any point from health at the one end, or from disease at the other. Any scale of gradations can be chosen. This is what is meant by a logical continuum. It is not a far step to see that the ultimate of disease is death and (applying the method of contrasting opposites) the ultimate meaning of health is life in the fullest and most complete and perfect sense of the word.

But a complication must be added if the model is to be adequate. Health and disease are not a simple pair of contrasting opposites like heat and cold. They are made up of immense numbers of components involving the body, the mind, and the spirit. Thus the imaginary line of the continuum becomes a rope of innumerable strands. At first sight this may seem a tortuous and perhaps pointless piece of speculation, but it does provide a basic model on which to found the reasoned structure of the principles of health education. We cannot indeed escape the necessity for such a model, and it is surely not contentious to hold that, if real advances in this subject are to be made, the pragmatic method, which has served its part, must be replaced by sound first principles.

Health, then, is a state which can be measured. In practice it is quite common to find approximate measurements being made. The medical examination of Service recruits, the much more exacting annual flying board for pilots, the life-assurance examination, and mass nutritional surveys are all examples of such approximations. These would all appear crude if compared to the total tests and measurements which modern medicine and psychology could apply, were there sufficient time and staff to do it. But they are enough for their especial purposes.

If a population large enough to give statistical significance is examined by such methods, a norm or average can be established which is a measure of the so-called " normal " health of the group within the limits of the measurements. But this is not to say that such a normal is the *best* or even a proper state of health for such a population. It is hardly necessary to point out that any such standard norm for a group selected from the British or any other people would fall far below the norm which could possibly be attained by attention to the rules of healthy living, good dentistry, complete nutrition, individual education in place of conveyor-belt methods, and so on. This is still true despite the enormous betterment in national health and fitness, expectation of life, stature, and the like, which have been brought about by preventive medicine in recent years—and which, we may well be proud to say, continued to improve during the war.

THE FIRST BASIC PRINCIPLE

It can be postulated, then, that such a norm of health exists for any population, and any deviation below this norm can be called negative, any deviation above, positive. The validity of this concept is demonstrated further by applying to the measurements a Gaussian curve, or indeed a frequency-distribution surface, although I shall not here extend this argument. But in the doctrine of positive health we have the first basic principle which is the essence of the new attitude in health education. It is that health is more than just the state of not being ill or of having no complaints or disabilities ; moreover " ordinary " health can be improved, though preventive medicine alone is not enough. The idea of positive health indeed points the way to constant improvement. The fullest use and enjoyment of life is only possible through the fullest use and enjoyment of health. This is at once true of body, mind, and spirit, which leads to the second basic principle of sound health education.

THE SECOND

This is the principle of holism, which I have found best expounded in that most important book *Holism and Evolution*, by General Smuts. To put it in the simplest way, if we talk about man in the physical sense, everyone will agree they understand what is meant ; but if we ask whether the term " man " includes his mind, or still more his soul, the argument starts. Yet from the holistic point of view we must regard man as a triad of body, mind, and spirit, just as psychologists (of the classical school at least) treat the mind as a triad of will, emotions, and intellect. But these are coexistent and interdependent. They cannot be separated one from the other except for dialectic convenience. They are not autarkic entities, for this would deny the principle of solidarity. Similarly, a study of anatomy without some physiology, especially neurophysiology, would be completely meaningless; while physiology could not be studied at all without at least an elementary knowledge of anatomy, for structure and function are inseparably related. Taking this circle method of categorising one stage further, the life of man could be described as a complex of the vegetative, motor, intellectual, moral, and reproductive—and these merge at some points. Part of the reproductive life of man is vegetative, part of it is concerned with morals and so on.

---

* A Chadwick lecture given in London on Oct. 30, 1945.

The main point is that, while we admittedly sectionalise knowledge and observations, this is only a matter of convenience, a sort of intellectual shorthand. "Separate" sciences are really closely enmeshed together. Advances in one produce alterations in the others, and there is a fluid equilibrium between them. So, too, the health of man is a whole thing and conterminous with his life. In studying it this should always be remembered, though commonly it is disregarded. For example, there is the type of fallacy we may call unitarian, such as is held by the faddist who has a diet cure for all ailments, or the person who treats every ill as imaginary, the so-called Christian Scientist.

It is necessary, then, for health education to be concerned with more than the inculcation of habits of cleanliness, temperance, exercise, and the like. The old saw "*mens sana in corpore sano*" has its corollary, "*corpus sanum in mente sana.*" Equally it must be remembered that the moral outlook is intimately connected with the health of both body and mind.

THE THIRD

The third principle of health education is not easy to name satisfactorily, but for present purposes we may call it the principle of motive or aim. It is designed to provide the force or energy for carrying out whatever procedures may be necessary to obtain health. The principle shows that in planning health education it is not sufficient to instruct people how to improve their personal or community health. It is necessary at the same time to convince them that it is really worth paying the price in effort, time, and perhaps money to obtain these benefits. This may at first sight appear so obvious as to be out of place in such a discussion, but unfortunately this is not so. Ask anyone if they want to be healthy, and the unhesitating reply is that they do. If this question is followed by a supplementary query about what they are now doing to promote their health, the answer is seldom so prompt.

It is true that some people will reply that they brush their teeth after meals and take open-air exercises when they can, and so on, and, in an occasional instance, if one has chanced on a faddist such an inquiry may open floodgates of enthusiasm. But only an insignificant proportion of the population make any effort to improve their physical and mental health and efficiency, unless illness has brought home to them the handicaps of disease.

Health education, then, must not only instruct but also convince people that health is worth having. The fact is obvious, as everyone will admit; but it is one thing to accept the validity of a general statement intellectually, and quite another to accept it emotionally as well. If our instruction is to produce the best results, it must create converts to the idea and imbue them with the fervour usually associated with the phenomenon of conversion. The formula then is:

(1) health is worth having,
(2) ordinary health can be improved by the expenditure of effort, and
(3) the expenditure of this effort pays real dividends.

I do not apologise for hammering at this point, obvious though it may seem. It is a common enough experience for people to be fired by the enthusiasm of a physical-culture expert on the radio, or perhaps a writer in a women's paper who promises beauty, charm, and a handsome husband for, say, five minutes' deep breathing a day. The course of exercises or massage or whatever it may be is started at once and kept up with fervour for at least three days. How reminiscent this is of the parable of the seed that fell on stony ground.

THE FOURTH

The fourth principle of health education is that of use. We must use our faculties, or they gradually fade. The Indian fakir may hold his arm above his head for years, and the muscles atrophy and the joints ankylose so that he cannot lower it even should he wish. A small boy may attain some competence at the piano in three or four years and then give it up, only to regret as an adult that he is just able to pick out "Swanee River" with one finger. These are examples of atrophy and disuse.

Few people develop and use their physical and mental powers in the most efficient way, and improvement is nearly always possible. The fact that athletes train specially before a big event is evidence of this. One can learn to walk a tightrope, or perform the difficult gyrations of the ballet dancer, if one sets one's mind to it. This does not mean that everyone should practice acrobatics or aspire to dance "Petroushka." It is instanced as an example of how physical capacities can be expanded (naturally, variations in physical and mental endowments make some people more fitted for a given activity than others). It is equally true of the mental faculties, whether one tackles the solution of mathematical problems or the harder task of swaying the House of Commons by impassioned eloquence. A combination of application and practice will improve one's facilities for dealing with either contingency.

This principle can be taken a step further, for it must be applied equally to the soul. Admittedly this is an unsatisfactory terminology, but the point to be made is that no person is completely healthy unless he has a sound moral discipline. Whether this be entirely from without, or from the wells of a man's own conscience, or a combination of the two, is irrelevant. The essence of the matter is that this moral discipline must exist. It has been remarked with surprise that during the war there was a decrease in neuroses, and the anticipated increase of mental ill health did not develop. Though it is easy to fall into the fallacy of post hoc, propter hoc, I am convinced that this reduction sprang from the same origin as did both the increase in the obvious unselfishness of people, and the warmer spirit of neighbourliness which was experienced especially in the bombed areas. The stern necessities of the time imposed a stronger moral discipline, and it is my opinion that this brought with it an improvement in mental and perhaps also physical health.

An obvious example of the value of moral discipline is in the realm of sex, where control is particularly difficult because of the deep roots of the instinct, and because of the repressions which have followed inevitably from the development of our culture. No-one of experience will deny that the sex aspects of life affect health in many ways, and equally those experienced in dealing with these problems will agree that the appeal to expediency is inadequate to determine healthy sex behaviour.

The rôle of moral discipline cannot be neglected; whether it is religious or strictly ethical is a matter for the individual about which one has no right to be dogmatic. It is, however, perfectly legitimate to insist not only that it is important but also that it is essential.

METHODS OF PRESENTATION

Despite an extensive search I have been unable to find any study which takes a comprehensive view of the methods of health education. The nearest is a book by Williams and Shaw entitled *Methods and Materials of Health Education* (New York, 1937), but it does not go into the detail which seems desirable. We need an evaluation of the relative effectiveness of the different methods of propaganda, from lectures to health weeks, particularly in respect of their impact on different age-groups or social groups and their applicability to the type of message which has to be given. A study of this nature is urgently needed. Techniques exist for carrying out such an investigation and have been developed widely in America in the field of merchandising research. Some information of this kind has been collected in relation to the Ministry of Health's successful campaign for diphtheria immunisation, but we need more general research.

A system of classification should be the first step in planning a campaign of health education, whether it be extensive or intensive. Different systems of classification may be used; for example, we may divide the problem into one of school and adult education. The former falls into three subdivisions of infant, elementary, and secondary, and university and technical college groups. The adult education would subdivide into general, comprising city- or nation-wide campaigns, and special, covering the instruction of small groups such as St. John Ambulance detachments, Women's Institutes, or patients attending a maternity and child-welfare centre. A second type of classification, parallel with the first, categorises the methods of instruction: oral (lectures, discussions, radio), visual (posters, advertisements, pamphlets, cinema, and exhibitions), and a comprehensive class of "health-weeks." One might include in this list the provision of amenities, such as swimming-baths, gymnasia, and sports grounds; but the implications of this are wider than the strict field of health education. A third system of classification, which would be useful in devising a scheme for health education, would be to enumerate the people and organisations involved in conveying the message—doctors, teachers, sanitarians, societies, and associations of various kinds.[1]

In the absence of an analysis of actual observations an opinion carries little authority; but, if only to invite contradiction, I say that the oral approach is more effective in adult education than is the visual; radio and lectures appear more effective instruments than do advertisements or posters. The success of Sir Wilson Jameson and of Dr. Charles Hill on the air has been outstanding. The position of the cinema, however, is anomalous, because it combines both types of instruction, yet in this medium the visual element predominates over the spoken. There are great potentialities in the development of health-propaganda films, but the standard of technical achievement in this field has not advanced so quickly as it might well have done. Admittedly the techniques are in the difficult stage of formulation, but with two exceptions the standard of health films I have seen is poor. The main reason appears to be that they have been made for non-commercial purposes under the direction of a committee of some society or association.

If the health film is to have an effective future, its structure must be regarded far more as a matter for professionals than has been the case in the past.

THREE LINES OF ACTION

There are three practical lines of action which are essential for making the most of health education.

The first is the provision, especially in the small centres of population, of more swimming-baths, gymnasia, and sports facilities. These are the workshops of health. In a recent visit to Germany I was impressed again by the way in which small towns were supplied with these amenities. Some hymn-writer once complained that it was not right that the devil should have all the best tunes. Equally we should not allow our fascist enemies to be able to claim that in such ways they did more for the people's health than does the stronghold of democracy.

The second point is the necessity for training more teachers in biological science and methods. Hygiene is an obligatory course in American schools, and many feel that this country lags deplorably in neglecting this study. But, unless fully trained teachers with a biological outlook are available, it is futile to introduce the subject. More harm than good would result if the ordinary teachers were given a *Reader in Hygiene* to go through with their classes. Prof. Lancelot Hogben has more than once put forward the demand that the universities' biological departments should review their instruction and train more students in general biology. The aim would be dual—to provide more biology teachers for schools, and to give all university students some knowledge of the science of life as an integral and essential part of cultural education. The educationist who would disagree with this proposal would be indeed a bold man.

Finally, there is no doubt in my mind that the churches should be coördinated more closely with the aims of national health. It has been shown that, from the holistic point of view, one must consider the moral aspect of human life with the physical and mental, and the point needs no amplification. It need only be added that the community group of the church congregation provides an admirable nucleus for concerted action. People of like conviction associate together easily, and the connexion with the church is advantageous in many ways. Within the church and outside it many voices are growing increasingly insistent that the church should pay a more vital contribution to the nation's life. Participation in health education is not merely another way in which this could be done. I submit that it is an essential duty for the churches to interest themselves in this matter, for life and health are a single whole, and no health education can be complete unless it includes in its ambit the physical, mental, and the moral activities of man.

Obituary

KARL NARBESHUBER

M.D.

Obermedizinalrat Karl Narbeshuber, who has died at Gmunden, Austria, in his 79th year, was a former president of the Austrian Medical Association. A true Austrian and a friend of the British, he was no doubt a marked man in the eyes of the Nazis, and no sooner did the Anschluss come than they took their revenge, treating him with cruelty and indignity. Hauled out of his bed on the first night he was thrown into prison, his life was threatened, his head and beard shaved, and he was deprived of his civil rights, property, and practice, and separated from his family. When Austria was freed he returned to his native town of Gmunden and once more devoted himself to his duties as Stadtarzt. But age and the privations of war had affected his health and he died on August 28.

A lovable man of wide learning and an exceptional linguist Dr. Narbeshuber did much for the British prisoners during the first world war. He often visited London, and many English doctors have enjoyed his agreeable hospitality in Austria.

Special Articles

BRITISH-SWISS MEDICAL CONFERENCE

THE conference organised by the Swiss Academy of Medical Sciences and the Royal Society of Medicine opened in the hall of the ethnological museum of the University of Basle on Sept. 16. Of the 280 doctors present more than 150 had come from the United Kingdom. Prof. A. GIGON, secretary-general of the academy, who first proposed a conference of this kind, introduced Prof. KARL WEGELIN, the academy's president, who said that the aim, as at last year's Franco-Swiss conference in Geneva, was to foster international relations. Welcoming the British visitors he recalled the ancient political and cultural bonds between the two countries which had remained unbroken since the seventh century. For Switzerland he expressed satisfaction at the end of the intellectual isolation enforced by the war. Bundesrat ETTER, on behalf of the Swiss Federal Council, paid a tribute to British tenacity in the war and recalled what had been done since then to strengthen the links between his country and Britain. He mentioned in particular Switzerland's help in the difficult post-war period—for example, she had invited 400 British children to stay in the country. Other speakers at the opening meeting were Mr. T. M. SNOW, the British minister in Berne, Monsieur PAUL RUEGGER, the Swiss minister in London, Prof. EDGAR BONJOUR, rector of Basle University, Regierungsrat Dr. MIVILLE, representing the authorities of Basle, and Lord AMULREE, representing the Minister of Health, who recalled the world's debt to Switzerland for the International Red Cross and for her fine conception of political liberty. Prof. J. B. HUNTER, Prof. J. H. DIBLE, and Dr. ALAN DRURY, F.R.S., of the British organising committee, emphasised the need for collaboration between the two countries and expressed thanks for Swiss hospitality.

After the formal opening Sir HUGH CAIRNS read a paper in German on Investigations on Head Injuries in Britain during the Second World War. Other papers were given in English with a simultaneous translation into German.

The afternoon session, under the chairmanship of Sir LEONARD PARSONS, was opened by Prof. LUZIUS RUEDI, who spoke on Acoustic Trauma, of which he distinguished four types which could be classified according to loss of function into two groups: the first group comprised noise trauma, report trauma, and certain blunt head injuries, and the second explosive trauma. He went on to describe an ear defender which he had designed, containing a resonator; its effect was to damp down frequencies between 2000 and 7000 cycles per second without seriously interfering with hearing. Repeated experiments had proved the complete efficiency of this defender which he suggested could be usefully applied in industry.

CIRCULATORY FAILURE

Dr. JOHN McMICHAEL (London) said that the old "back-pressure" view of cardiac failure was based on the mistaken idea that the veins are inert tubes. Thirty years ago Starling showed, by means of his heart-lung preparation in the dog, that the most important single factor determining cardiac output is the venous inflow; up to a certain point elongation of the cardiac muscle increases its capacity for work, but beyond that point output falls. Harrison, in 1935, suggested that the output of the heart might not be very much lowered in heart failure, and in 1938 Dr. McMichael reached much the same conclusion. In the early stages of failure the resting output may not be significantly lowered, but the capacity to increase output is diminished. Only later does the output fall, and then usually to not less than half the normal resting value. The measurement of right auricular pressure by a ureteric catheter, first practised by Cournand in New York, has proved a safe and effective means of estimating cardiac output and filling pressure, and has been employed without mishap in over 500 cases by Dr. McMichael and his colleagues. The new method has confirmed that in the ordinary forms of heart disease, from valvular defects or hypertension, the resting output is maintained and the first rise of venous pressure takes place when the output is only slightly below the normal average. This rise is thus not the back-pressure effect of a falling output but a compensatory mechanism to maintain the optimum output as long as possible. In the later stages of failure the venous pressure is considerably raised and the cardiac output reduced to about 3 litres a minute. In the failing heart digitalis reduces the venous pressure and increases the cardiac output, though in the normal heart the reduction of venous pressure is accompanied by a fall in output. In auricular fibrillation rate-reduction is not of primary therapeutic importance; the major benefits of digitalis are achieved by reducing the venous pressure, and a mechanical reduction of venous pressure will produce as great an improvement as digitalis.

Discussing the conditions in which a high cardiac output is required to oxygenate the tissues, Dr. McMichael said that Sharpey-Schafer has shown that when the hæmoglobin falls below 30 % the cardiac output may need to be doubled and this can be accomplished only by a high venous pressure and a simultaneous increase of pulse-rate. At this stage the patient's condition is precarious, and venous congestion and œdema may be pronounced. Digitalis will lower venous pressure and cardiac output, so reducing the supply of oxygen to the tissues and making the patient worse; transfusion, on the other hand, will raise the right auricular pressure but reduce the cardiac output, and this may result in death from heart failure, owing to pulmonary œdema. If transfusion is necessary to save such a patient's life it must be given slowly, possibly combined with digitalis. The danger lies in raising the venous pressure, which is set at the optimal level, so the anæmic patient should be treated with liver or iron, as far as possible avoiding transfusion. In *cor pulmonale* the output is usually high for a reason similar to that in anæmia—i.e., the available oxygen in the arterial blood is considerably reduced. Here digitalis is not only useless but dangerous. High-output failure has recently been observed with generalised Paget's disease, in a man of 66. The blood-flow through the normal skeleton, measured by Prof. O. G. Edholm with the plethysmograph, is about 100 c.cm. a minute, whereas in Paget's disease the total skeletal flow is between 3 and 4 litres a minute. The circulatory state is thus a result of the enormous increase in skeletal circulation.

The classical pre-war conception of shock has been modified; the view that blood is pooled or trapped in some part of the vascular system has been discarded. Hæmorrhage is the major factor in war wounds; hæmoconcentration does not occur except in burns and crush injuries and some types of abdominal injury. Wallace and Sharpey-Schafer have shown that, after the loss of 1000–1200 c.cm. of blood, full blood-dilution is not attained for some 40 hours. Blood-volume may be reduced in chronic anæmia, and this state is associated with an increased cardiac output. In hæmorrhage the pressure falls in the great veins, the cardiac output falls, the pulse-rate is accelerated, and the peripheral resistance is increased. After this first phase there may be a vasovagal reaction, owing to sudden vasodilatation in the arterioles of the skeletal musculature, with reduction in pulse-rate and blood-pressure. Recovery from this reaction, whose purpose is obscure, may be hastened by 'Methedrine.' D. W. Richards has shown that in the average case of shock the cardiac output seldom falls below 3 litres a minute; the deep fall in blood-pressure is due mostly to lack of vasoconstriction, for which hitherto ill-defined factors in addition to the vasovagal reaction may be responsible. Oxygen is worthless as a means of overcoming the defects of sluggish blood-flow in shock. Recent observations suggest that in shock with overwhelming infections the regulation of venomotor tone may be impaired and a suprarenal cortical mechanism may be involved somewhere in the chain of events. Other types of non-surgical shock—e.g., the collapse of diabetic coma and coronary thrombosis—should be approached by the new methods.

Observation suggests that peripheral vasodilatation and a high cardiac output are present in the early stages of diabetic acidosis.

ŒSTROGENS IN CANCER

Prof. E. C. DODDS (London) recalled the steps which led to the synthesis of stilbœstrol, hexœstrol, and dienœstrol as the result of collaboration between Sir Robert Robinson and his colleagues in Oxford and Professor Dodds's own department at the Middlesex Hospital. Animal experiments have shown that these three substances can replace all the known activities of the naturally occurring œstrogens. They have now been widely used clinically for the treatment of menopausal symptoms, amenorrhœa, and dysmenorrhœa, and for the termination of lactation. Their great advantage lies in the fact that they are active by mouth and cheap to produce. The possibility of using œstrogens in the treatment of carcinoma of the prostate was first mooted by Huggins and his colleagues in 1941. Castration for the relief of prostatic carcinoma was originally advocated by John Hunter, who observed that the gland would shrink when the testes were removed. However, the operation had so many objections from the patient's point of view that it was rarely performed. In the four years from 1939 to 1943 Huggins treated 69 patients with advanced carcinoma of the prostate by castration combined with the administration of œstrogens. The synthetic œstrogens were found to be perfectly suitable for this purpose. Œstrogens were administered to patients who did not obtain a long remission of their symptoms after castration and to those in which the serum-level of acid phosphatase, though considerably reduced, did not drop to normal. In most cases the treatment relieved pain and frequency of micturition, and improved the patient's general condition: in some cases there was a reduction in size of the primary tumour and the secondary deposits. Other workers in Britain and America have treated carcinoma of the prostate with œstrogens alone and have confirmed Huggins's findings. About 95% of cases respond in some degree, but the improvement is not always maintained and many cases will have to be classed eventually as delayed failures. No serious worker in this field would claim that synthetic œstrogens will cure carcinoma of the prostate, since if treatment is interrupted the disease begins to progress again as before. But the treatment is more than mere palliation; the benefit obtained, even if only temporary, constitutes a definite arrest if not a regression of the disease. Side-effects reported from the administration of œstrogens include swelling, tenderness, or soreness of the breasts, nausea, vomiting, and occasionally soreness of the testes. As a rule these effects are not serious enough to require cessation of therapy and they are generally far outweighed by the benefits obtained. The dosage of synthetic œstrogens is 1 to 5 mg. per day.

The exact mode of action of œstrogens in carcinoma of the prostate has still to be worked out. The changes in the serum-level of acid phosphatase indicate that the metabolism of the malignant cells is interfered with. This enzyme is present in large quantities as a secondary sexual characteristic in the adult prostate, and its presence depends on the activity of androgens. The serum-level of acid phosphatase was shown in 1936 to be abnormally increased in some men with metastatic carcinoma of the prostate, and in 1941, Huggins demonstrated that the level can be reduced either by orchidectomy or by the administration of œstrogens. He also pointed out that in many cases a malignant prostatic tumour is due to hypertrophy of adult epithelial cells which are acted on by androgens. He therefore deduced that if the activity of androgens could be inhibited, either by removal of the testes or by the administration of œstrogens, then the growth of these cells would be interfered with and the tumour and possibly the secondaries would regress. A possible explanation for the occasional failure of œstrogen therapy is that these tumours may be due to the malignant development of other cells over which androgens have no control. A further explanation is the existence of an extragonadal source of androgens, possibly in the adrenal cortex. It is still doubtful whether, in addition to the inhibition of androgens, the synthetic œstrogens exert some definite controlling influence on the malignant cells themselves. Biopsies on cases before and after treatment with stilbœstrol have revealed characteristic changes in the cells, different from those caused by irradiation.

Until the action of synthetic œstrogens in prostatic carcinoma is explained it is impossible to forecast the likelihood of success in carcinomas of other parts. Some success has been obtained in carcinoma of the breast—of 168 cases reported by various workers, 41 were improved, and in 6 the improvement was "spectacular"—and again the question arises whether the improvement is due to a change in the endocrine balance or to the specific action of the drug on a certain type of cell. A committee has been set up by the Royal Society of Medicine and the British Empire Cancer Campaign to investigate a large number of cases of carcinoma treated with synthetic œstrogens and to follow them up over a long period. The report of this committee cannot appear for some years, but it is hoped that it will yield valuable information on the type of case most likely to be benefited and the reasons why such benefit is to be expected.

A VISIT TO FINLAND

W. P. GURASSA
M.B. Lond.

F. L. JACKSON
M.B. Lond.

WHILE on a visit to Stockholm, in March of this year, we were assisted by the British Council to visit Helsinki, so that we could see something of the medical work there and meet some of the students and young physicians.

The journey across the Baltic was an entirely new experience. The sea was frozen almost all the way over, so that even with the assistance of icebreakers progress was slow. Several times the ship jammed in the ice and we arrived at Abo many hours late. But the weather was wonderful—cold and crisp with brilliant sunshine. This, with the spectacle of myriads of tiny islands, made the journey a delight.

The train journey to Helsinki from Abo was not so pleasant. We left Abo early in the morning, without any breakfast. Finnish restaurant food is bad. We were offered some tiny scraps of rye bread with a little fish roe on them, but could not face them, so we sustained ourselves with some sugar which we had brought from Sweden. Later, when the train stopped for a quarter of an hour at a station we ate some potato, which in our then famished state seemed extremely good.

At Helsinki we were met by the assistant professor of radiology from the General Hospital and two students, one of whom was a Swede who spoke fluent English and acted as our guide during our short stay. We were taken immediately to see Professor Holsti, the professor of internal medicine, who entertained us generously, both at the hospital and at his home. He spoke excellent English, having studied for some years in America, and in true American fashion had prepared for us a very full programme designed to show us as much as possible.

At 8.30 on the first morning we attended the radiology department, where we saw some films showing opacities in the lungs of patients with typhus, early in the attack before the appearance of the rash; these opacities are fleeting, and should be sought specifically. Another interesting film of the chest showed the characteristic ground-glass appearance of asbestosis. We were impressed by the quality of the work and the enthusiasm of the staff.

Next we were conducted round the Polyclinic by Professor Holsti. We saw several cases of Buerger's disease, one in a patient of 17 years, and were told that it is common in Finland. Another condition of which we heard much was dibothriocephalus infestation, and we were each presented with specimens of the worms to bring back to England. This, however, was probably unnecessary, since after eating some of the fish obtainable in Finland—raw—we probably now harbour sufficient of the parasites ourselves! The morning concluded with visits to special departments for the treatment of cancer, chiefly by radiotherapy, and the newly formed allergy clinic under the direction of Dr. Erikson-Lihr, the first of its kind in Finland.

A national scourge in Finland is tuberculosis, the annual mortality-rate being 17 per 10,000. Dr. Severi Savonen, who is in charge of the tuberculosis services in Finland, told us that the war had brought a halt to the previous decline in the mortality-rate. As elsewhere in Scandinavia, B.C.G. inoculation is widely used, on a voluntary basis. Infants are inoculated, where possible, in the obstetric clinics soon after birth, and special homes are provided for the isolation of infants from open cases. Savonen believes that inoculation produces excellent results and does not give rise to ill effects. At Christmas time, money for anti-tuberculosis work is raised by the sale of coloured stamps which are stuck on the letters in addition to postage stamps.

Later, Professor Holsti initiated us into the mysteries of the Finnish steam bath (sauna), which is widely acclaimed as responsible for the toughness of the Finns, endowing them with a spirit of unbounded energy and stubborn determination (sisu). Many people have their own steam baths, and Professor Holsti's was in a rough wooden shack in his garden. In the corner burned a fire, and water drawn from a near-by trough was cast on to it so that clouds of steam billowed into the room. It is the custom to lie outstretched on wooden shelves and perspire freely. From time to time one washes with cold water, or beats oneself with a sheaf of leafy twigs which have been dipped in cold water. Then the heat increases. When one feels sufficiently relaxed one runs outside and rolls in the cold snow for a minute or two. This closes the skin vessels and facilitates drying. We dried without this severe preliminary act, but watched amazed while the professor's son and our Swedish guide performed it.

Next morning we visited the neuropsychiatric institute at Lappvik, where we were conducted round the wards by Dr. von Bagh who addressed us in French. This institute is over 100 years old, but its construction is good. The wards and corridors are light and airy, and, as in most Scandinavian clinics, there are few patients in each room (3–6). We saw many cases of disseminated sclerosis, and it was claimed that fairly good temporary results were obtained by pyretotherapy. Prefrontal leucotomy has recently been introduced in Finland, being used particularly for the treatment of chronic obsessional states. We saw the first case so treated at this hospital.

We learnt something of the poor food situation both from personal experience and from accounts given to us by medical men. Bread is of the poorest quality, dark, coarse, and bitter, and is strictly rationed. Milk is rationed to 600 c.cm. per person per week, butter to 500 grammes a month, and no other fat is obtainable. Meat is rarely seen. The staple diet consists of potato, bread, and fish. There is, however, a large black market in food for those who can afford it. Most of the people look thin and ill clad, and Helsinki, once proudly called the "White City of the North," shows signs of neglect and dilapidation.

On our last evening we were entertained to dinner by the Medical Association. We gave them some account of our medical studies in England, and many of them expressed a desire to visit England later on. We have brought back many pleasant memories of Finnish hospitality.

The Finns look with confidence and determination to the future—their "sisu" is no myth—and they will strive hard to restore prosperity to their land.

ARMY REFRESHER COURSES IN GERMANY

At the end of the late war the university clinic at Göttingen, with its 2000 beds, was found to contain a remarkable selection of clinical material. In the ensuing months Major J. M. McFie and Major H. O. McLaren, the medical and surgical specialists attached to a nearby casualty clearing station, paid repeated visits to the clinic, with which they were so impressed that they suggested that refresher courses should be held there for medical officers, particularly those on general duty; such courses, they thought, might encourage postgraduate study. The proposal was warmly supported by the director of medical services, and the consulting physician and surgeon, 21 Army Group; and the first course was held from Nov. 18 to 24, under the direction of Major McLaren, who was later succeeded by Captain P. E. H. Jones.

CLINICAL TEACHING

The clinical teaching was given by the university staff. Few of these spoke fluent English and most officers had difficulty in following explanations in German; direct interpretation was tedious and sometimes misleading. A German-speaking specialist officer, R.A.M.C., was therefore appointed chairman-interpreter. Case-notes were abstracted and translated into English, and the translation was circulated with the original notes in German, which, with even slight knowledge of the language, provided a good deal of information.

Cases were chosen with straightforward clinical signs to illustrate common disorders. In the medical and surgical clinics each officer was allotted a long case, with twenty minutes for examination, followed by five minutes in which he summarised his findings before the whole class, and a further five minutes for the professor's comments. Short cases were also shown. Midwifery and gynæcology were handled on much the same lines. Post-mortem demonstrations were included; and for a short time each day the Germans demonstrated their own recent advances. The morning break and a further period at the end of the day were used for discussion: time at the clinic was often saved by deferment of individual questions until these meetings.

The German method of teaching differs from the British. With the British method interest is sustained by the discussion of history, symptoms, and signs, and differential diagnosis, and by the liability of anyone suddenly to be asked a question. By the German method the diagnosis is often given first and followed by a discourse in which the grounds for the diagnosis are discussed. Much the same results are achieved in the end by the two techniques. For the courses the British method was used.

OPEN LECTURES

The last afternoon was usually occupied with a lecture or demonstration by either the consulting physician or surgeon, or a medical officer with special knowledge of some subject. These were open lectures which might be attended by anyone, including sometimes nurses from the clinic; as many as 150 have been present. The arrangement that has proved most satisfactory has been for the lecturer to speak slowly and clearly in English, and for each listener to have a German translation in front of him. Experience has shown that translation of German case-notes into English is best undertaken by an Englishman, but that the German version of a lecture to be given in English should be made by a German.

Medical officers attending the clinic have had the chance of seeing German methods and of obtaining clinical instruction in aspects of medicine which during their service they had had little opportunity of studying. The reading of textbooks, which has been increasingly practised since the end of the war, has been given added impetus by these courses, which have been greatly appreciated; and the German staff has worked hard to make them successful. Seven courses have been held at Gottingen, and they are being continued at Hamburg, which is more readily accessible. In addition, courses in midwifery are being held for nursing officers. It is intended that these courses shall be retained as a permanent feature of training in the B.A.O.R.

In England Now

A Running Commentary by Peripatetic Correspondents

DURING the war one had either to "stay put" or to keep moving round the world at an enormous pace. After nearly four years of the former, I spent the later part of the war in almost incessant travel. I gather that we itinerants were generally spoken of as "swans"—i.e., creatures who flit aimlessly from place to place sticking their long necks out. One's journeys ("really necessary" or otherwise) were often brightened by unexpected meetings with old friends. For instance, when I arrived at a general hospital in North Africa the first officer I met greeted me by my christian name—much to my surprise, for I certainly did not recognise the prosperous, mature individual who spoke. I discovered that we had been new boys at the same prep. school together, and that he had changed inwardly a good deal less than in outward appearance. And the O.C. of the same hospital turned out to be our own family physician, a territorial with whom I had lost touch since his call-up in 1939.

Then there are the people one is always meeting. One eminent medical major-general has done even more "swanning" than I have. Within a period of eighteen months our orbits have touched, quite without premeditation, at Prestwick airport (he en route for the U.S.A.; I on my way home from Africa), London, Manchester, Colombo, Melbourne, Delhi, and finally back in London again. I am convinced that if I ever reach the North Pole I shall find him squatting there. Then there are the others that one just misses. I have been trying to meet one scientist for years, and have been within a week of him in every continent of the globe.

It is often impossible to avoid the use of such clichés as "it's a small world." I remember meeting one American major at a laboratory in the heart of the Rockies. A month later we met again, this time at Myitkyina, on the Irrawaddy, in Burma, after he had crossed the Atlantic and I had crossed the Pacific.

* * *

Yes, as I was saying when you cut me off on Sept. 7, the practitioner in the Medically Overcrowded Area (M.O.A.) is perhaps less like a vulture than like that aged man a-sitting on a gate, of whom the poet sang:

> I shook him well from side to side
> Until his face was blue.
> "Come, tell me how you live," I cried,
> "And what it is you do."

True, neither a Royal Commission nor anyone else has, in so many words, asked him; but there can be no doubt of the shaking. It continues with increasing violence and perhaps can be taken to imply the question. Anyhow by the time the cyanosis has reached ante-mortem intensity it will be hard to give an articulate and dispassionate reply. That hour is not far distant. Better try now.

The essential feature of a M.O.A.—at least of mine—is that although it contains a fairly intimate mixture of citizens of every social and economic class a good number are what is called "educated"; some have comfortable incomes and some have inherited that sane and comely fashion of living which made Maurois call the English gentleman "la type la plus sympathique du monde." The combination of all this with the famous medical overcrowding has an almost wholly beneficent effect on the quality of medical practice. Comparatively speaking there is time for good work, rewards for doing it, and effective penalties for not doing it. Our all-round competence is, I am sure, less than that of many of our colleagues in country towns, to whom I take my hat right off; we are not their equals in resourcefulness, nor, I suspect, in power of endurance; they would beat us hands down at surgery, and I judge that they are better at team-work—your typical M.O.A. doctor works alone—but there are provinces of medicine in which I believe we hold the field.

It is fashionable to assert that the whole profession takes little or no interest in personal preventive medicine; it never sees the healthy patient and seldom even the early symptom; its concern is solely with declared disease. How different things will be when we have health centres! Perhaps they will, but in the meantime all these things which the whole profession neglects to do it does in fact daily, hourly, and as a matter of course in the M.O.A.

To set aside half or three-quarters of an hour for discussion of Susan's aversion to food and Willie's to sleep, for the terminal or annual overhaul of three children returning to school; to determine whether or why Mr. Smith has grown thinner, or why Miss Jones has been coughing for four weeks; to give Mr. Brown the once-over because he hasn't seen a doctor for several years—all the variations on these and kindred themes make up, except in seasons of epidemic, a large proportion of our daily work.

Now I am far from asserting that this is indeed the medicine of the future. For the practitioner it is exacting, difficult, rather tedious, full of pitfalls, and not very rewarding either in cash or in things discovered or things prevented. It can never be a main fountain of health, and for the patient it has potentialities for ill as for good. But it is the medical reformer's white-headed boy, it is perhaps the chief characteristic product of the M.O.A., and when the reformer has had his way with us the M.O.A. and all its works will be gone. Forsooth, a pretty paradox! But each man kills the thing he loves; and perhaps reformers are no exception.

What else do we do? The doctor's daily job, with perhaps six hours over in the week to divide between reading, writing, committees and societies, the family, and the cultivation of a garden or an art. Six? Well, perhaps eight, and, being on good terms with our professional neighbours, we get a yearly holiday without importing a locum. What really attracts us to the spot? Not fortune-hunting, but, this excluded, it is anyone's guess. My own is that if we were examined the greatest common factor in our make-up would be a certain slowness—we are not quick thinkers or quick workers; we must have time. Unquestionably we are individualists, with the qualities and defects of that species. Probably most of us set rather a high value on the pleasant manners and way of life to which most of us have been brought up and prefer a small income in a place where our wives and children can enjoy these things to a large one where they cannot. We may believe, too, that we can do our best work where we are; and we may be right.

What of our patients—the citizens of the M.O.A.? Are they privileged? I think they are; but not, as the planners preach and possibly believe, by receiving some costly drugs or magic treatments denied to others. They have, and exercise, free choice of the most genuine sort; they reap the very real benefits of competition. Each of us knows that if he lets his patient down that patient can turn to his neighbour. It is very salutary knowledge. They enjoy the almost priceless boon of being able to ask for an appointment to discuss any matter in which they think we can help them. To extend this last benefit to "insured persons" without much more encouragement than any government of the last 35 years has given must seem to most people impracticable. It seems so to me; but most men do not readily divide themselves, no-one can stop the diffusion of excellence, and there can be no doubt that all the citizens of the M.O.A. have some share in the refreshing fruits of medical overcrowding.

Nor, I think, can diffusion stop there. So long as there is somewhere a standard of excellence, there will be a tendency everywhere to attain it; destroy the standard and the tendency must cease.

Perhaps our manner of practice in the M.O.A. has no excellence, but if it has look your last on it, for it is scheduled for demolition. The shaking or "softening-up" by gently persistent public detraction and by alternate promises of sweets and smacks is well advanced. On the Appointed Day all our patients, I suppose, become "panel patients" and we can take our choice. We can try to maintain our standards under the familiar conditions of government contract practice with this egregious addition, that whereas it must clearly be both illegal and wrong to take fees from our own patients it will be legal and, in the eyes of authority, positively meritorious to see other men's patients behind their backs, give them an "independent opinion," and lift a fee for it. The whole foundation, in fact, economic and ethical, of our manner of practice will on that day be *bouleversé*.

But we have a choice. We can reject the sweets, accept the smacks, and take, bow in hand, to the merry green wood, outlawed for sabotage. A grim choice.

But think of the M.U.A.—the Medically Undercrowded Area. So I will; and I will think of their houses. I am shocked at the inequality of housing. Some live in mansions, some in hovels; but I have a plan. On an appointed day all who live in houses better or worse than an approved middle shall be housed in prefabs. Then, all their dwellings being alike demolished, the specially good brick, stone, timber, and tiles of the mansions can be used to fortify and increase the stock from which the approved middling houses in which all shall hereafter live are to be built. When all are in them, there being none better all will have the best.

What? You do not like my plan? You cannot bear that a house architecturally good and beautiful should be destroyed? You think it is part of our common inheritance, that it has value as a pattern? You don't think the bricks and stone of the mansions will go very far? You think they will be scarcely detectable? Sentimental dreamer! Hide-bound Tory! Enemy of the People! Upholder of privilege! Fascist reactionary! *Bourgeois!*

* * *

As I was doing a locum near, I went on pilgrimage to Selborne. I met the vicar, who told me a story of Gilbert White (see portrait), who was a small and precise man. When he was a subproctor at Oxford he found an undergraduate lying drunk and naked in the street and next morning he lectured him but did not punish him because even in his cups he had folded his clothes neatly by his side.

I touched the limes White planted to hide the carnage of the butcher's shop, I trod reverently on his grandfather's grave in the chancel of the village church, I admired the window—except its garish top—put up to his memory, mosaiced with many birds, and then went out to his own grave in the churchyard. It was pleasantly untended, hawkbit flowered on it and there were two thriving colonies of red ants. He would have liked that. I let them sting me, striving at a molecular continuity and kinship. May the peace that comes from the things of the earth, which he got and gave—and gives—be with him still.

* * *

I wonder how many people are making full use of the results of war-time research to increase their comfort when on holiday in Britain. Our biting insects and mites may not be the vectors of disease (and anyhow this year's weather has not encouraged cold-blooded creatures to breed) but many a holiday has been ruined by midges, gnats, or harvest-mites. D.M.P., or dimethyl phthalate, was well known to the troops in south-east Asia and elsewhere as an insect repellent, but how many have thought of it at home? And many who have had to go through the whole drill of smearing their clothes with D.B.P. in scrub-typhus areas have never thought of doing anything like that when they are attacked by harvest-mites. Yet one can protect oneself pretty thoroughly from these creatures by smearing a couple of c.cm. (or should we say ml.?) of either benzyl benzoate (any of the anti-scabies remedies containing it will do equally well), or of dibutyl phthalate on one's socks and perhaps round one's trouser bottoms. The remedy remains effective for several washes, so one application at the start of the harvest-mite season should do the trick.

HOSPITALS DAY.—This year hospitals day in London is to be Oct. 8. All who can help are asked to write at once to the appeal secretary of their local voluntary hospital, or to Lord Luke, chairman of Hospitals Day, 36, Kingsway, London, W.C.2.

Public Health

Typhoid at Aberystwyth

THERE are now further details of the outbreak of typhoid fever at Aberystwyth. Several people in the town were taken ill on July 22, 23, and 24, with headache, pyrexia, and cough; and on July 26 the first case of typhoid was identified. During the next few days the condition was diagnosed serologically in several further people whose history appeared to incriminate ice-cream sold by a particular vendor. A spot-chart kept at the Public-health Department indicated clearly that, apart from water, ice-cream sold by this man was the only foodstuff common to all patients admitted to hospita The milk-supply in the town is zoned; and the fact tha all the patients happened to belong to different zone was a great help in ruling out milk as the source o infection.

The county medical officer of health arranged for th isolation of all cases of typhoid, either in the loca hospital or in hospitals in South Wales, and an ambulanc service was organised. These arrangements worked smoothly.

The sale of ice-cream by the suspected vendor wa stopped on July 29; his blood gave a positive Wida reaction to *Bact. typhosum* (H) at a dilution of 1 in 320 and to (O) at 1 in 80; it also reacted to Vi at 1 in 80 Specimens of fæces grew no enteric organisms, bu *Bact. typhosum* was grown from the man's urine and wa later found to be of type C. He was admitted to an isolation hospital for further investigation and treatment By this time *Bact. typhosum* had been isolated from th other patients; they were all of type C.

Cases of typhoid have since been identified in th neighbouring district and elsewhere in the country in people who had lately been to Aberystwyth and partaken of ice-cream, many of them naming the particular seller. Altogether 76 cases have been notified in other areas.

The course of the outbreak is illustrated by the weekly notifications from Aberystwyth.

Week ending ..	July *27*	Aug. *3*	Aug. *10*	Aug. *17*	Aug. *24*	Aug. *31*	Sept. *7*
Cases notified ..	1	43	29	18	10	1	3

So far only one case has been reported with an onset more than 23 days after the sale of ice-cream by the carrier was stopped. This patient was a contact with his wife who had been ill for some days before calling in a doctor. Up to Sept. 8 only one other contact appears to have contracted the infection.

The diagnosis of cases and the tracking of carriers has been much facilitated by the presence of an Emergency *Public-Health Laboratory in the local hospital.* The immense value of such a laboratory in remote areas has been clearly demonstrated.

Infectious Disease in England and Wales

WEEK ENDED SEPT. 7

Notifications.—Smallpox, 0; scarlet fever, 668; whooping-cough, 1824; diphtheria, 284; paratyphoid, 42; typhoid, 21; measles (excluding rubella), 1321; pneumonia (primary or influenzal), 202; cerebrospinal fever, 33; poliomyelitis, 19; polio-encephalitis, 5; encephalitis lethargica, 0; dysentery, 86; puerperal pyrexia, 136; ophthalmia neonatorum, 74. No case of cholera, plague, or typhus was notified during the week.

The number of service and civilian sick in the Infectious Hospitals of the London County Council on Sept. 4 was 843. During the previous week the following cases were admitted: scarlet fever, 42; diphtheria, 38; measles, 17; whooping-cough, 27.

Deaths.—In 126 great towns there were no deaths from measles or scarlet fever, 2 (0) from enteric fevers, 6 (0) from whooping-cough, 2 (0) from diphtheria, 31 (0) from diarrhœa and enteritis under two years, and 5 (2) from influenza. *The figures in parentheses are those for London itself.*

Bradford reported the 2 fatal cases of an enteric fever.

The number of stillbirths notified during the week was 236 (corresponding to a rate of 26 per thousand total births), including 34 in London.

Letters to the Editor

B.C.G.: THE NEXT PHASE

SIR,—Your timely leader of Sept. 14 raises a number of points of practical significance. As one who has recently visited the Scandinavian countries,[1] where I had a unique opportunity for seeing the work myself, I may perhaps make a few preliminary observations. I hope to publish my experiences more fully later.

I found the enthusiasm for B.C.G. in Norway, Sweden, and Denmark widespread, and most people were convinced of its efficacy as a valuable adjunct in the control of tuberculosis, although several public-health experts emphasised that vaccination should in no way interfere with established anti-tuberculosis measures. I was struck, too, with the little control work done on B.C.G. in any of the three countries, and, while I can understand and appreciate the difficulties encountered in this connexion, I hope that in this country we shall have an opportunity for remedying this defect in order to produce reliable statistical evidence of the value of immunisation. Such control work as I saw—admittedly the figures were comparatively small—was convincing; but I agree with your statement that "only the most carefully compiled figures in significant quantity will satisfy the statisticians."

Although we rightly look to chemotherapy for striking results in the future I think it is true that in this country a somewhat neglected field of preventive medicine has been protection against tuberculosis by active immunisation in tuberculin-negative subjects, more particularly among persons in areas of high tuberculosis morbidity and mortality—e.g., children of tuberculous families, students, nurses, and other young employees in general hospitals and sanatoria where exposure is great and protection difficult.

Taking into account the difference in the clinical features of tuberculosis in this country from those I noted in Scandinavia I felt that their work was highly encouraging. Few will question Heimbeck's original assertion—for which he deserves the highest credit—that tuberculin-negative nurses show a higher incidence of tuberculosis than those who are tuberculin-positive. I was privileged to see with him in Oslo a further extension of this work which more than corroborated his earlier observations.

Nothing that I saw impressed me more than the work of Prof. Arvid Wallgren, now professor of pædiatrics in Stockholm, who has certainly been the pioneer of B.C.G. vaccination in Sweden, having started his work in Gothenburg in 1926. His confidence in the clinical value of B.C.G. remains undaunted although he recognises its limitation and admits that it is not of use except in primary lung tuberculosis. Unfortunately even Wallgren has, however, had little opportunity for control work.

With regard to the respective merits of B.C.G. vaccine and the vole-bacillus vaccine of Wells, which you rightly suggest is running B.C.G. very close, Wallgren's observations to me are not without interest. He urged, from his own experience of vole vaccine, that it would be of the greatest scientific interest and value if we in this country were to use it. He gave me the impression that it would eventually supersede B.C.G. I think there is good evidence for the belief that both methods of inoculation (*a*) are harmless to humans, (*b*) increase resistance to tuberculosis, and (*c*) are of value only in tuberculin-negative subjects. B.C.G. has stood the test of time in many countries and its harmlessness has been established by its practical application on a large scale in many parts of the world. Nevertheless, there is good evidence that the vole-bacillus vaccine has the following advantages over B.C.G.: (*a*) it is apparently a more potent immunising agent; (*b*) its virulence is more stable (the varying virulence of B.C.G. in Norway, Denmark, and Sweden was noteworthy, and I was told on more than one occasion that some of the strains were losing their virulence); and (*c*) there is reason to believe that tuberculin allergy following vaccination with it was greater and occurred earlier than that following B.C.G.

Let me add a word about the method of administration of the vaccine. Wherever I went in the three countries the intracutaneous method devised by Wallgren was regarded as the quickest, most reliable, and practical; and it afforded a more accurate measure of the dosage. All observers were emphatic that complications such as significant abscesses never arose when the injection was truly an intradermal one but did arise when the technique was bad and some of the solution had been injected subcutaneously. I was given, especially in Denmark, an opportunity of assisting at the B.C.G. vaccine clinic and I can corroborate this view from what I saw. Such authorities as Herzberg in Oslo, Wallgren in Stockholm, Anderson in Gothenburg, and Winge in Copenhagen strongly favoured this method. The so-called transcutaneous method, either by scarification or multiple puncture with the Birkhaug-Rosenthal instrument, seemed to meet with little favour for a variety of reasons which space will not permit me to deal with here, and I had an excellent demonstration of it by a great authority.

From these impressions I think one is justified in urging that enthusiasm should be tempered with caution. Wisely handled there is little doubt that immunisation should prove a useful weapon. We have a unique opportunity for starting afresh with adequate control experiments and filling in the gaps which Continental and other workers, often through lack of opportunities and no fault of their own, have omitted. We must furnish sound statistical proof, beginning for preference with a selected group of the population who are exposed to unusual risks of tuberculous infection. May I, therefore, strongly support your plea that the Ministry of Health set up, as soon as practicable, an authoritative committee under the auspices of a body such as the Medical Research Council to institute a clinical trial of what they regard as the most effective method of tuberculosis vaccination?

London, W.1. PHILIP ELLMAN.

TREATMENT OF MENINGITIS

SIR,—Dr. Gaisford's letter of August 17 should serve as a useful corrective to over-enthusiasm. Whenever a new remedy is discovered for any particular malady, there seems to be a regrettable tendency to discard the older and often well-tried remedies. Recent examples of this appear to be syphilis and perhaps meningitis, particularly cerebrospinal fever. In the latter, it is surely a retrograde step to employ intrathecal therapy unnecessarily. What then are the indications?

Possibly the greatest triumph of the sulphonamides has been in the treatment of cerebrospinal fever, including acute and chronic meningococcal septicæmia, and the great majority of cases—95% according to Dr. Banks (Sept. 7)—respond excellently. With the exception of cases of sulphonamide intolerance and those rare cases of the ordinary types of the disease which fail to respond to sulphonamides, there is no real indication for the use of penicillin, at any rate intrathecally, in the non-fulminating varieties of cerebrospinal fever.

The fulminating varieties can be divided, perhaps a little arbitrarily, into those cases which are often dead within a few hours—Waterhouse-Friderichsen syndrome—and the type with well-marked meningitis which progresses to a fatal termination in about twenty-four hours. I have no experience of the use of penicillin in the former type of case, but its efficacy by whatever route it is administered (and it should certainly be given) would seem doubtful. In the second type of fulminating case, if after a few hours on combined sulphonamide and systemic penicillin therapy the patient's condition is still rapidly deteriorating, then, in accordance with the evidence so far available, intrathecal penicillin is indicated. I have not had cause to regret this, and two such injections are usually sufficient. It is important to remember, however, that such cases comprise a very small percentage of the total.

Similarly, penicillin is indicated in pneumococcal, streptococcal, and staphylococcal meningitis; and, in those cases which do not soon show improvement on systemic administration of the drug, the intrathecal route is again indicated. I have successfully employed this method in pneumococcal meningitis when, despite previous sulphonamide medication, the general condition continued to deteriorate. Obviously, as few intrathecal injections as possible should be given and one hopes that heroic procedures such as trephining the skull for the intraventricular injection of penicillin will not be embarked on indiscriminately.

---

[1] My visit was sponsored by the public-health committee of the county borough of East Ham, for whom I act as consulting physician for tuberculosis and diseases of the chest, and to whom I am greatly indebted.

It seems then that the indications for intrathecal penicillin are strictly limited and uncommon, and that the mere fact of the cerebrospinal fluid being opalescent or turbid or the cell-count increased are no indications for such therapy. The immediate risks are obvious—for example, the introduction of penicillin-resistant organisms—and the possibility of delayed sequelæ, such as *postmeningitic* headache, should not be forgotten. Clearly, much judgment and skill are required in deciding when this route of administration is advisable.

EFFECT OF PHOSPHATE ON CARBOHYDRATE ABSORPTION IN SPRUE

SIR,—Many will learn with regret, on reading his letter of Sept. 14, that Professor Maegraith has had to abandon his experimental work on sprue. I take this opportunity of making one comment. In both his letter and the preliminary communication referred to[1] he gives the impression that impaired phosphorylation as a factor in the pathogenesis of sprue was an idea emanating from himself, whereas the arguments supporting this belief were put forward by me four years ago,[2] though doubtless Professor Maegraith has overlooked the point.

London, W.1.
HUGH S. STANNUS.

CIRCULATION IN THE KIDNEY

SIR,—The preliminary communication by Trueta and his colleagues in your issue of August 17 (p. 237), and their demonstration of a diverted renal circulation following upon stimulation of afferent nerves, is at once interesting and important. The investigators are to be congratulated on their new technique, which has made their observations possible, as much as on the results so far described, and it is to be hoped that the histological investigations will be such as clearly to demonstrate, in the rabbit, the presence and character (or absence) of vasa recta and the other non-glomerular blood-channels which have been described.

It is indeed strange to read in your leading article (p. 239) that "the arrangement and functions of the vasa recta . . . have been relatively neglected," when, until this present claim of Trueta and his colleagues, it has been generally agreed that the work of Huber (1906–07), Gérard (1911), Traut (1923), and MacCallum (1926) had disproved such non-glomerular medullary supply described by Ludwig (1852), Virchow (1857), and Golubew (1893)—just as the röntgenographic studies of Katzenstein (1911), Liek (1915), and Gross (1917) had disproved the existence of large arteries arching over the pyramids, the arcuate arteries of von Ebner (1899).

In 1889 Bradford demonstrated vasoconstriction within the kidney, and resulting shrinkage, on stimulation of the splanchnic nerves, and similar reflex contraction by central stimulation of the cut sciatic nerve and vagus, and confirmed the earlier observations on the relation of the splanchnics to the output of urine by Claude Bernard (1859), and Cohnheim and Roy (1883). Burton-Opitz and Lucas (1908) showed that section of the splanchnics increases the blood-flow through the kidneys, whereas stimulation decreases the flow; and Burton-Opitz (1908) showed that the right and left splanchnics were distributed to the right and left kidneys respectively. In the frog, Bieter (1930), confirming the work of Richards and Schmidt (1924–25) and Richards (1925), recorded that stimulation of the sympathetic fibres to the kidney, and of the central end of a cut sensory nerve, such as the sciatic, produced great vasoconstriction throughout the kidney: the majority of active glomeruli stopped, showed stasis and gradual emptying of the capillaries but no inflow of red cells, while "The glomeruli which do not stop as a result of splanchnic stimulation sometimes appear to show a flow at an increased speed, as if a certain amount of arterial blood must get into the kidney regardless of the number of glomeruli that are open for flow." Andrews (1927) noted anuria in dogs following the release of tight ligatures from the leg, and Bieter repeating this in the frog noted reduced glomerular capillary activity, an effect which was removed by section of the splanchnics. Bieter (1935) observed that "it is likely that in the frog the vasomotor control of the kidney vessels is not as highly developed as it is in mammals and man, and consequently, ascending the scale, the effects would possibly be more powerful."

When it is recalled that in human cases of severe renal cortical necrosis, in which even the columns of Bertini are involved, the medulla is not necrotic and a great many of the deep (juxtamedullary) glomeruli show no stasis, that they and their wide efferents (which pass to the medulla direct) are in fact functioning, it is not unnatural to conclude that this reduced or diverted (medullary) circulation may well be maintained by these glomerular efferents—without requiring the existence of vasa recta or of the corticomedullary arteriovenous shunts described by Steinach (1884) and Spanner (1938) to explain the viability of the pyramids and the anuria.

Like circumstances obtain in the rabbit in experimental renal cortical necrosis. In the normal rabbit kidney 5–7 % of the contained blood is present in the glomerular capillaries where it is changed about 5 times per second and has a probable velocity of 1–2 mm. per second. Thus if 85 % of the glomeruli are involved in the necrotic process of renal cortical necrosis, the remaining 15 % (large juxtamedullary glomeruli) can accommodate the whole normal glomerular capillary volume, simply by all of their capillary loops coming into play, should the minute-volume remain unaltered (personal observations on glomerular circulation). The circuit-time in this "medulla-diverted" circulation will be reduced too, for the deep glomeruli and their efferents are largest and egress is free, resulting medullary blood-channels are short and wide vis-à-vis the cortical capillary rete. In other words, from a consideration of the hæmodynamics of the renal circulation in the rabbit, it is possible to suggest that the degree and character of the altered renal circulation, as outlined by Dr. Trueta and his colleagues, and the "redistribution of blood-flow within the kidney" discussed by Professor Maegraith (p. 213), could be maintained by a circulation via the deep (subcortical or juxtamedullary) glomeruli only, the cortex being relatively avascular, by vasoconstriction of the peripheral arterial vessels in response to afferent (sciatic or other) stimuli.

But vasa recta and their loops are described, and we await with interest the first clear demonstration of these vessels (in situ), and possibly also of other non-glomerular supplies and shunts which from time to time have been described.

MYTH AND MUMPSIMUS

SIR,—Many of us must be grateful to Dr. Forbes for his destructive article in your issue of August 31. I have often thought that destructive thought is a valuable property. The vast accumulations of rubbish, many of them monuments to the more foolish moments of great men, need a great deal of shaking; and I do not think Dr. Forbes has gone nearly far enough.

He writes that there is only one criterion for the value of any therapeutic procedure—does it work with patients? Many theoretically sound treatments fail because they work only if the patient is isolated in an artificial environment. Take the magic bullets of Ehrlich and their later modifications. In actual practice this treatment sometimes failed, perhaps by the accidents of treatment but often by default or irregular attendance for the long and tedious courses of injections. Because of these limitations the magic looked shabby in the light of day. The failure in many cases was due to the fact that a man was primarily a lorry driver, a hotel clerk, or a commercial traveller—in other words, a human being—and only secondarily a patient with syphilis.

Any treatment that fails to recognise the human nimal as a whole and its place as a social unit tends to artial success. The immobilisation of young children or long periods seems a sorry sort of treatment for a ving creature; it fails in that it treats a part by maltreating the whole. Activity is an essential part of health, and far more care should be taken not to prescribe unnecessarily restrictive measures; nor should a man be taken off work without the most careful consideration. He often does better if he stays at work.

The same applies to diets. A man should enjoy his food because enjoyment is an essential part of good digestion. Very few diets are enjoyable. Is it not a fact that what we are really enduring in our ordinary dietary is not lack of calories but unmitigated English cooking? Why does the gastric-ulcer patient have his meat minced? A more horrid food than minced meat cannot be imagined, and given a reasonable set of teeth the natural act of chewing suffices; chewing, moreover, promotes digestion.

The trouble in gastric-ulcer diets is partly due to simple-minded arguing from pathology. Here, we say, is an ulcer in the stomach, it must not be irritated by pips, fruit skins, stalks, meat extracts, alcohol, or tobacco. But patients are often willing to experiment and some find beer, as well as other supposed irritants, gives them no discomfort. Many manage a practically normal diet except for greasy foods. Arguing from pathology, well-lubricated greasy foods should slide harmlessly over an ulcer. They apparently do not. Nevertheless, pathology is a valuable corrective in medicine. Unfettered by it Freud trampled on the fairy stories of Greece and raised some extraordinary myths. Worse still, the psychoanalytical school is becoming respectable—it even appears in the Brains Trust!

It seems a pity to blow up some of these picturesque ruins, but it may be necessary; besides it gives healthful pleasure to those who cannot stand bunk, especially when buttressed by authority.

Oxford. G. WHITWELL.

CALF SERUM FOR TRANSFUSION

SIR,—No doubt war-time conditions prevented Dr. Massons, of Barcelona, having access to my paper on despeciated bovine serum (*Brit. med. J.* 1944, i, 73) to which you refer in your annotation. A material somewhat similar to P.C.P. was produced in the department of surgery, University of Liverpool, by the addition of formalin and ammonia to bovine serum. The essential difference in the final production of the solution is, however, that in despeciated bovine serum the heating process is taken to 72° C only, while in P.C.P. the solution is heated to 100° C. Experiments which we did showed that the agglutinins are destroyed at 72° C, associated with changes in the globulin fraction. At this temperature the changes in the albumin fraction are small and the material still exerts an osmotic pressure of 120–160 mm. of water compared to the figure of 150 mm. of water found for pooled citrated plasma. Material heated above this temperature shows a steady decrease in the osmotic pressure until at 100° C it has none at all. The readings were taken by the micro-method of Krogh and Nakazawa against mammalian Ringer solution. It is thus difficult to see how P.C.P. can have any more beneficial effect than normal saline.

The original reason for the preparation of despeciated bovine serum was to produce a substitute for human plasma that would have been of value had the supplies of human plasma not been sufficient to meet war-time needs. When it was apparent that human material was available in sufficient quantities, further production of despeciated bovine serum was stopped. It was administered safely, however, to over 200 patients by myself and others in amounts of one pint or more, the largest volume given to one patient being 16 pints. I would reaffirm that despeciated bovine serum prepared by the Liverpool method is non-toxic, non-antigenic, free from antibodies, of an equivalent osmotic pressure to citrated human plasma, retained in the circulation, and eventually metabolised.

Liverpool. F. RONALD EDWARDS.

LATENT PERIOD IN KALA-AZAR

SIR,—The following case well illustrates the fact, pointed out by Armstrong,[1] that there may be a long latent period before kala-azar produces symptoms. This seems to be fairly well known, but is nowhere else emphasised in the published work. Manson-Bahr[2] suggests six months as the upper limit of the incubation period, and Strong[3] and Scovel[4] suggest four months as the maximum; but none of these authors draws attention to the further latent period which may occur before symptoms appear. Manson-Bahr notes that the disease may remain latent for many months in artificially infected dogs, and Sweeney et al.[5] describe a case with a "presumptive latent period of two years," as in the present case.

A private, aged 26, served from April, 1940, to December, 1943, in Eritrea, Egypt, Libya, Palestine, and Syria, and from December, 1943, to February, 1944, in Italy. His disease probably originated before December, 1943, after which date he was stationed north of Naples.

In the summer of 1945 he noted that his belt seemed tight on exercise, but otherwise he felt perfectly fit. In October, 1945, he was admitted to hospital with a history of coryza for about a month, and of headache, shivering, and sweating for several days.

He was thin and pale, with a yellowish tinge to the skin, and had a swinging temperature rising to 100°–103° F every evening, accompanied by profuse sweats. A large tumour was present in the left hypochondrium extending to below the level of the umbilicus. The nature of this tumour remained in doubt, it being considered to be either the spleen or the left kidney. An intravenous pyelogram did not help, because no dye was excreted on the left side; and an attempt at ascending pyelography was unsuccessful. The liver was not palpable, and no enlarged glands were felt.

Blood-count: red cells 2,030,000 per c.mm., Hb 48% (14·5 g. per 100 c.cm.), colour-index 1·1; white cells 2650 per c.mm. (polymorphs 50%, lymphocytes 25%, monocytes 10%, eosinophils 1%, myelocytes 3%, myeloblasts 3%, unclassified 2%). Plasma protein 7·55 g. per 100 c.cm.

Sternal puncture gave a marrow count of polymorphs 8%, myelocytes 40%, metamyelocytes 3%, lymphocytes 0, monocytes 0, normoblasts 6%, premyelocytes 6%, myeloblasts 4%, erythroblasts 33%, megaloblasts 0. No Leishman-Donovan bodies were seen.

Other investigations all proved negative, and further blood-counts and sternal punctures showed a similar picture, Leishman-Donovan bodies still being absent from marrow smears. Patient's condition altered little, and the high evening temperature and profuse sweats continued.

In view of the continued doubt in diagnosis, laparotomy was done on Nov. 23, after transfusion with packed cells. The tumour was found to be a grossly enlarged spleen. No other abnormality was found in the abdomen. Splenic puncture

2. Manson-Bahr, P. H. Manson's Tropical Diseases, London, 1945, p. 156.
3. Strong, R. P. Stitt's Diagnosis, Prevention, and Treatment of Tropical Diseases, Philadelphia, 1944.
4. Scovel, F. G. *Ann intern. Med.* 1944, 21, 607.
5. Sweeney, J. S., Friedlander, R. D., Queen, F. B. *J. Amer. med. Ass.* 1945, 128, 1020.

was done, but no Leishman-Donovan bodies were found either on direct examination of the biopsy specimen or on culture.

On Dec. 18, as there was no improvement, it was decided to treat the case as kala-azar, and a course of stilbamidine 0·075 g. followed by 0·15 g. daily to a total dosage of 2·25 g. was given. The sweating began to decrease after six or seven days, but the temperature did not respond till the thirteenth day of the course, when it dropped suddenly and thereafter remained low.

On Dec. 25 culture of marrow blood in Lache-dextrose sloppy agar with defibrinated rabbit blood at 24° C grew "distinct leptomonas forms of Leishman-Donovan bodies, fresh preparations showing characteristic motility."

Progress was slow but excellent, the anæmia improving and the spleen decreasing in size. In February, 1946, patient was given a course of urea stilbamidine. In March his general condition was most satisfactory, the spleen being just palpable and the anæmia clearing well. In April, 1946, he reported numbness of forehead, cheeks, and lips, but was otherwise well.

The chief points of interest in this case are the long latent period, the difficulty in diagnosis, and the dangers of Vth nerve involvement when stilbamidine is used.

A. P. NORMAN.

Hospital for Sick Children, Great Ormond Street, London.

⁂ L. E. Napier, writing in the *British Encyclopædia of Medical Practice* (London, 1938, vol. VII, p. 342), mentions a patient who developed symptoms of kala-azar after being away from any endemic area for 18 months.—ED. L.

CHILDREN WHO SPEND TOO LONG IN BED

SIR,—Dr. McCluskie, in his letter of Sept. 14, replying to my criticisms of his article, has so far retracted as to say that the time of sleep required by a child may vary by "an hour, or more, or less": this period of an hour was not mentioned in the original article. He reaffirms his statement, with which no-one will disagree, that many children spend too long in bed: but he does not explain how the mother with two or more small children, and little or no domestic help, can follow the "detailed directions" which he thinks necessary for sleeping as well as feeding.

He has also failed to produce any evidence for the dogmatic statements in his article that "if a baby has an hour too much sleep during the day it will certainly cry during the night," and "variation by even 15–30 minutes from the amount of sleep each particular child requires at each month produces violent change of behaviour." If "years of experience with children" lead him to these conclusions, I can only assume that his experience has been limited to dealing with rather unusual children. A perceptive mother recognises that external factors such as the activities of the day, physical and mental, produce variations in the amount of sleep required: and I think it a facile assumption that the behaviour disorders which Dr. McCluskie describes can be so directly related to lack or excess of sleep. In his *Contributions to Analytical Psychology* Jung says that "the neuroses of children are rather symptoms of the parents' mental condition than a genuine disease of the child."

I should be glad to know the signs and symptoms of "a nation-strangling matriarchy."

London, W 11. CATHERINE STORR.

SIR,—Dr. McCluskie gives good advice concerning hours of sleep for children. One cannot make a child sleep to suit one's convenience. I suggest that, if he wakens early, the child might be encouraged to play quietly with some toys, after being made comfortable, until his mother is ready to dress him and give him his breakfast. I consider that an average baby of a few months requires more sleep than Dr. McCluskie prescribes. A baby wakened too long before his feed will get tired and fretful. A contented baby soon learns to adjust his own sleeping hours to his individual needs. He will lie playing with his hands, and later practising making new noises, and a busy mother will be unaware when he wakened or fell asleep again. He should be as happy in his pram as anywhere, though he will enjoy a regular kicking time to exercise his limbs: this time can be increased in length to correspond with his abilities.

Eastbourne. JOAN BRIGDEN.

EPIDEMIC THROMBOPHLEBITIS

SIR,—There seems little doubt that the condit described by Lieut.-Colonel Manson-Bahr and Dr. Charters (Sept. 7, p. 333) is the tropical primary phlebiti described in 1941 by one of us[1] as occurring in Norther Rhodesia. Since then this disease has been st further, and our observations on 71 cases will sh be ready for publication. Manson-Bahr and Charte state that they find no histological cause for the thrombosis. The histological appearances in the vein wa described in 1941 were acknowledged then as obviousl abnormal (A. C. L.) but the interpretation of these an of a subsequently observed chronic case with giant cel (cf. Manson-Bahr's case, p. 334) was at last made clea by a recent opportunity to study what is certainly th essential lesion. It had come to be appreciated (A. C. F. that only a short stretch of the vein was primaril involved, and microscopy of this zone has now reveale a peculiar form of inflammation characterised by extrem proliferation of young capillaries in the disrupted medi of the vein, and by the presence of phloxinophil intracytoplasmic inclusions.

ROYAL COLLEGE OF PHYSICIANS OF LONDO

SIR,—A letter in the *British Medical Journal* o August 31 (p. 313) has focused attention once more o the statutes, by-laws, and regulations of the Roya College of Physicians and the justifiable discontent which they arouse.

As is well known, the present regulations do not allow members to take any part in the running of the college. In fact, they are specifically debarred from doing so under by-law 118, which says ". . . they shall not be entitled to any share in the Government, or to attend or vote at General Meetings of the Corporation." Surely this state of affairs is quite out of date, and in view of the great changes now taking place the time is ripe for the college to broaden its representation with a view to ensuring that members obtain a voice in its counsels and deliberations on common-sense, democratic lines.

The college, instead of remaining a mere academic institution, should become a living force, capable of exercising a profound influence for good on various medical, social, and educational problems confronting us and pressing urgently for solution.

The first step in this desirable aim must surely be the provision of facilities for adequate representation by the members, who should be given every encouragement to form their own standing committee, &c., and take an active part in the management of the college. Obviously one of the important tasks of any newly elected committee should be to go into the question of the revision of the existing regulations concerning the election of fellows.

EFFICACY OF THE PENICILLINS

SIR,—Your leading article of Sept. 14 directs attention to the desirability of ensuring that penicillin used [illegible] medicine shall, as far as practicable, consist only [illegible] penicillin II (G). For some time past we have been fully conscious of this, and, by the choice of appropriate media and precursors, together with the use of selective extraction procedures, we have secured approximately 90% of penicillin II (G) in our product. As a further precaution, our vials are now filled so that, within the limits imposed by existing assay procedures, we believe them to contain the stated content of penicillin II (G) —i.e., if a vial is claimed to contain 100,000 units of penicillin, it contains not less than that number of units of penicillin II (G), and any small proportion of penicillin IV (K) which may be present is additional. In this manner the practitioner is assured of the full dosage of the penicillin on which he relies for therapeutic efficacy.

Notes and News

CRICHTON ROYAL FELLOWSHIPS

TODAY some inside knowledge of the working of a modern psychiatric hospital is essential for the consultant, and many established specialists have been spending a busman's holiday visiting their colleagues at the Crichton Royal, Dumfries. To fill this gap and to hasten the fuller training in psychiatry lately recommended by the Royal College of Physicians, the board of directors of the Crichton Royal have set up three fellowships, in addition to the ordinary staff of the hospital. The fellows will receive training in all branches of clinical psychiatry, including fever treatment, prolonged narcosis, electric convulsion therapy, insulin therapy, and leucotomy. They will have opportunities to work in the outpatient and child-guidance clinics, to join in the work of the psychiatric social worker, and take part in home and follow-up visits. Each fellow will be attached to one of the senior psychiatrists who will be responsible for his instruction, and later patients will be allotted to him. He will also attend all clinical staff meetings and become familiar with the management of different wards, the legal problems of psychiatry, and routine psychological testing. The fellowships, which carry a salary of £400 a year in addition to residential emoluments, will in the first instance be tenable for one year from Feb. 1, 1947. Forms of application may be obtained from the physician superintendent of the hospital and should be returned not later than Dec. 16.

ART FOR THE ILL

Adrian Hill, an artist, had tuberculosis, and during his long boring convalescence found how quickly he could make the hands of the clock move by sketching in pencil or water-colour. When he got up he shared this device for passing the time with his fellow patients, and, partly no doubt owing to his own ability to instruct and interest, found many who could equal his pleasure in making pictures, if not his technical skill. He has written a likeable book (*Art versus Illness*, George Allen and Unwin, 10*s.* 6*d.*) about this small start in a new type of occupational therapy and its considerable developments. He found a starved taste for pictures in many unlikely quarters, and in others a bent for original work which needed only opportunity to grow. His experiment seems likely to become an accepted part of treatment in some sanatoria and should be seriously considered in all. His amusing and constructive little book, illustrated with many of his own drawings and those of his patient-pupils, is well worth reading with this idea in mind.

DELINQUENCY ON THE SCREEN

THE approved schools usually carry on their constructive work without much publicity, but their achievements are so notable that they should be widely understood. *Children on Trial*, a Crown Film Production now showing at the Academy Cinema, furthers this end and also adds to the high reputation of British documentaries. The stories of three delinquent young people are outlined without any emotional emphasis, and the result is not only moving but intensely interesting—far more so, indeed, than the average thriller. The delinquencies are not understated, the extenuating circumstances kept in perspective, the approved school with its scope for growth of mind, body, and spirit presented fairly. The cast includes only two professional actors, one of whom plays the delinquent girl, the other the headmaster of the approved school. The other actors are taking their natural parts, the boys being played by Liverpool and Birmingham schoolboys. The boy playing the main delinquent has a natural economy of expression and gesture which could not be bettered. Doctors should try to see this informative film.

Family Planning Association

The association is holding a conference on Infertility, on Sept. 21 and 22, at the National Institute for Medical Research, Hampstead, N.W.3. At 3 P.M. on Saturday, the 21st, Dr. Mary Barton will speak on the Biology of the Cervix, and Dr. G. I. M. Swyer on the Rôle of Hyaluronidase in Fertilisation. There will be demonstrations at 5 P.M., and afterwards Dr. Audrey Smith and Mr. A. S. Parkes, F.R.S., will read a paper on Antigenic Properties of Spermatozoa. On Sunday, the 22nd, at 11 A.M., Dr. Margaret Hadley Jackson and Mrs. C. Harvey will speak on Experience with A.I.H., Dr. Muriel Rose on the Prognostic Value of Semen Examination, and Dr. Raymond Cross on Habitual Abortion. Further particulars may be had from the secretary, 69, Eccleston Square, London, S.W.1.

University of Edinburgh

Mr. D. M. Douglas has been appointed lecturer in experimental surgery in the university, and deputy director of the Wilkie Surgical Research Laboratory. He has also been elected to the staff of the Royal Infirmary as an associate assistant surgeon.

University of Glasgow

Dr. Thomas Anderson, physician superintendent of Knightswood Hospital, Glasgow, has been appointed full-time lecturer in infectious diseases in the university. The lectureship which the university has set up after consultation with the city corporation is the first full-time one in this country and carries with it the title of visiting physician to Knightswood Hospital, so that the holder may have adequate clinical material for teaching and research. Dr. Anderson will also become consultant in infectious diseases to the corporation. The salary scale of the lectureship is to be £1200–£50–£1500.

Dr. Anderson, who graduated M.B. at the University of Glasgow in 1928, held a resident appointment at the Western Infirmary and later became deputy physician superintendent at Ruchill Fever Hospital. He was elected F.R.C.P.E. in 1940, and obtained his M.D. with honours last year. His published work includes papers on the use of chemotherapeutics in infectious diseases, particularly pneumonia.

Royal College of Obstetricians and Gynæcologists

On Sept. 27 the honorary fellowship of the college will be conferred on Mr. Victor Bonney in recognition of his services to British gynæcology.

Travelling Fellowships

The Medical Research Council have awarded Rockefeller medical fellowships for 1946–47 to the following:

SHEILA T. E. CALLENDER, M.D. St. And., M.R.C.P., graduate assistant, Nuffield Department of Clinical Medicine, Oxford.

C. E. DENT, M.B. Lond., M.R.C.P., research assistant, medical unit, University College Hospital, London.

A. M. JONES, M.B. Manc., M.R.C.P., Leverhulme research scholar (Royal College of Physicians), University and Royal Infirmary, Manchester.

A. M. MACDONALD, M.D. Edin., F.R.C.P.E., department of pathology, Edinburgh University.

J. E. MORISON, M.D. Belf., lecturer in morbid anatomy, Queen's University, Belfast.

F. T. C. PRUNTY, M.D. Camb., M.R.C.P., lecturer in chemical pathology, St. Thomas's Hospital medical school, London.

F. F. RUNDLE, M.D. Sydney, F.R.C.S., surgical specialist, R.A.M.C., lately chief assistant and registrar, Westminster Hospital, London.

JOHN SWINNEY, M.C., M.D., M.S. Durh., assistant surgeon, department of urological surgery, Newcastle-on-Tyne General Hospital.

The council have also awarded a Dorothy Temple Cross research fellowship in tuberculosis to:

T. F. JARMAN, M.D. Durh., assistant tuberculosis physician, Welsh National Memorial Association.

International Society of Medical Hydrology

This society is holding its first post-war meeting at Buxton from Oct. 4 *to* 6. The speakers will include Dr. J. van Breemen (Four Causal Factors of Rheumatic Disease in Connexion with Medical Hydrology), Mr. R. Whittington (Plasma Viscosity), Dr. Victor Ott (Present Swiss Concepts of Rheumatism and Physical Medicine), Dr. Abraham Cohen (Physostigmine in Rheumatoid Arthritis), and Dr. Louis T. Swaim (American Concepts on Arthritis). Further particulars may be had from Dr. Donald Wilson, 28, The Circus, Bath.

Service Prizes

The R.A.M.C. Prize Funds Committee announce that the following prizes are open for award in 1947 after a lapse of some eight years due to the war:

Leishman Memorial Prize.—A silver medal and £30 for the best work in any branch of medicine, surgery, or the allied sciences, or in connexion with the general duties of the R.A.M.C. or of the Army Dental Corps.

Alexander Memorial Prize.—A silver medal and £70 to the officer who during the year has done most to promote the study and improvement of military medicine, surgery, hygiene, or pathology.

Parkes Memorial Prize.—A silver-gilt medal and £60 to the regular serving medical officer who has done most to promote the study of naval or military hygiene.

The Alexander and Parkes prizes are not open to officers on the staffs of the Royal Naval Medical School, the Royal Army Medical College, or the Army School of Hygiene. In making these two awards first consideration will be given to original articles published in a medical journal, and part authorship will not justify the recommendation of an officer for these prizes.

Recommendations should be sent through the usual channels, with copies of original articles and reports, to reach the hon. secretary of the committee, R.A.M. College, Millbank, London, S.W.1, by Dec. 31.

Middlesex Hospital

The annual dinner will be held at the Savoy Hotel, London, W.C.2, on Friday, Oct. 4, at 7.30 P.M.

Nutrition Society

The society is holding a conference on The Work and Aims of the Food and Agriculture Organisation on Saturday, Sept. 21, at 10.30 A.M., at the London School of Hygiene, Keppel Street, London, W.C.1. The speakers will include Sir John Orr, F.R.S., *director-general of F.A.O.*; Mr. D. Lubbock; Dr. P. Lamartine Yates; Dr. W. R. Aykroyd; and Miss E. Fautz.

Medical Society of the L.C.C.

There will be a clinical meeting of the society on Thursday, Oct. 3, at 3 P.M., at Dulwich Hospital, S.E.22, when the staffs of Dulwich and St. Olave's Hospitals will demonstrate cases.

Association of Industrial Medical Officers

The annual general meeting of the association will be held at the London School of Hygiene, Keppel Street, W.C.1, on Friday, Oct. 18th, at 5 P.M., and will be followed by a dinner at 7.30 P.M. On Saturday, the 19th, at 10.30 A.M., Dr. Donald Hunter and Dr. R. S. F. Schilling will speak on Industrial Medicine in the U.S.A.

St. Thomas's Hospital

Dr. A. L. Crockford has been appointed secretary of the medical school in succession to Dr. R. J. C. Thompson, who has resigned.

Brazilian Honour

The Brazilian order of the Southern Cross has been conferred on Sir Alexander Fleming, F.R.S., who presided over the Inter-American medical congress which met in Rio de Janeiro this month.

Return to Practice

The Central Medical War Committee announces that Dr. Kenneth O. Black, 27, Weymouth Street, W.1 (Langham 3336), has resumed civilian practice.

Births, Marriages, and Deaths

BIRTHS

DUTTON.—On Sept. 10, in Manchester, the wife of Captain G. C. D. Dutton, R.A.M.C.—a daughter.

HACKETT.—On Sept. 8, the wife of Dr. C. J. Hackett, of Wendover, Bucks—a son.

HIBBERT.—*On Sept. 13, in Liverpool, the wife of Dr. Geoffroy Hibbert—a son.*

HUSTON.—On Sept. 7, the wife of Lieut.-Colonel John Huston, *R.A.M.C., of Edinburgh—a daughter.*

LILLICRAP.—On Sept. 12, at Lincoln, the wife of Dr. Charles Lillicrap—a son.

LOGIE.—On Sept. 9, at Aberdeen, the wife of Mr. Norman Logie, F.R.C.S.—a son.

MARRIOTT.—On Sept. 11, in London, the wife of Dr. Ian Marriott—a son.

MAY.—On Sept. 8, at Chatham, the wife of Surgeon Lieut.-Commander R. T. May, R.N.—a son.

PORTER.—On Sept. 6, at Woking, the wife of Dr. H. L. Porter—a son.

SMITH.—On Sept. 7, in London, the wife of Dr. J. F. Smith—a son.

VICARY.—On Sept. 12, Dr. Patricia Vicary (née Shaw), the wife of Dr. Peter Vicary, of London, W.14—a son.

WYNNE.—On Sept. 7, the wife of Dr. Roger Wynne, of Banbury—a daughter.

YUDKIN.—On Sept. 7, the wife of Dr. Simon Yudkin—a daughter.

MARRIAGES

AMBROSE—CLAVERING.—On Sept. 11, in London, Gordon Ambrose, L.M.S.S.A., to Sheila Clavering.

BENNETT—MELLING.—On Sept. 7, at Baylham, Harold Stanley Bennett, M.B., R.A.F.V.R., *to Barbara Hunter Melling.*

REID—SHARPE.—On August 31, in Calcutta, Grainger Wilson Reid, lieut-colonel R.A.M.C., to Ruth Hilda Sharpe, Q.A.I.M.N.S./R.

WALKER—JONES.—On June 14, in Nairobi, D. O. Walker, major R.A.M.C., to Mary Jones, Q.A.I.M.N.S./R.

DEATHS

BEEVOR.—On Sept. 15, at Burnham, Bucks, Charles Ferrier Beevor, M.A., B.M. Oxfd.

GOLDEN.—On Sept. 8, at Ilford, Michael Bruce Howard Golden, M.R.C.S.

GRAY.—On Sept. 12, at Dalkeith, Midlothian, George Douglas Gray, C.B.E., M.D. Edin., late lieut.-colonel R.A.M.C.

HILL.—On Sept. 8, at St. Mary Bourne, Hampshire, Alfred Arthur Hill, M.D. Durh.

HOWIE.—On Sept. 7, Mary Evelyn *Howie,* M.B. *Durh., of Gosforth,* Newcastle-on-Tyne.

PATON.—On Sept. 9, at St. Albans, Herts, Richard Reid Kirkwood Paton, M.B. Glasg., D.P.H.

SLAYTER.—On August 22, in Madras, Edward Wheeler Slayter, C.M.G., D.S.O., M.B. Edin., late colonel R.A.M.C., retd., of Halifax, Nova Scotia.

STREET.—On Sept. 8, at Crowborough, Ashton Street, M.B. Camb., F.R.C.S., lieut.-colonel I.M.S., aged 82.

WILSON.—On Sept. 10, in Cardiff, James William Albert Wilson, M.D. Belf.

WARNER, O. F., L.R.C.P.E.: M.O. (grade B), Trinidad.

WILLIS, J., M.D.: M.O., Hong-Kong.

Dr. E. H. VAN SOMEREN.—*A footnote* in a recent book o memoirs states that Dr. van Someren, who practised i Venice from 1898 to 1913, suffered from melancholia an committed suicide in Venice. His obituary notices (see *Lance* 1913, i, 793; *Brit. med. J.* 1913, i, 589) make it clear tha he died at Syracuse after a short illness at the age of 41; h was a diabetic and died in coma after contracting influenza.

PERFORATED PEPTIC ULCER

TREATED WITHOUT OPERATION *

HERMON TAYLOR
M.A., M.D., M.Chir. Camb., F.R.C.S.
SSISTANT SURGEON, LONDON HOSPITAL; SURGEON, KING GEORGE HOSPITAL, ILFORD, CONSULTING SURGEON, ENFIELD WAR MEMORIAL HOSPITAL

IT has long been a rule of surgical practice that erforated peptic ulcer should be treated by immediate peration to suture the perforation and drain the perioneal cavity. It is, however, questionable whether all ases of perforation should be lumped together indisriminately in this way. The gravity of the crisis depends ot so much on the fact of the perforation as on the ikelihood of a fatal peritonitis. But the factors which determine this issue—the interval between perforation and treatment, and the amount and character of the leakage from the stomach—vary within the widest limits. Automatic surgical intervention takes no account of his variation, nor does it recognise the existence of the natural defence mechanism within the peritoneal cavity.

It must not be forgotten that the peritoneum, with its copious blood-supply and lymph drainage, its endothelial cells and phagocytes, is specially adapted to overcome infection. It can sterilise and absorb a considerable quantity of infective fluid, provided the contamination is not repeated before the peritoneum has had time to recover from the damage suffered in the process. To state this is to put the problem of perforated ulcer in its proper perspective. Obviously if an infective peritonitis is already established as the result of delayed treatment or gross flooding of the peritoneal cavity there is no alternative to the classical operation, since drainage is essential. But if the contamination which has taken place can be checked at the source without operation, before it has overcome the peritoneal defence, no drainage is necessary, and the patient will recover spontaneously.

A method of achieving this is described here, the effect of which is to reduce the problem in any one case of perforated ulcer to an assessment of the degree of leakage that has taken place. The decision to interfere surgically will depend on this assessment, but in the great majority of cases it will not be necessary, as the present case-reports show.

DEVELOPMENT OF THE CONSERVATIVE METHOD

It will perhaps be useful to describe how I came to make this departure from established practice.

In operating on early perforations in the usual way, I repeatedly found that the peritoneal fluid was sterile on culture, and therefore I began to dispense with the drainage-tube more and more, without encountering any case of delayed peritonitis as a result. But the crucial experience was that from time to time there occurred cases in which I opened the abdomen only to find the erforation already sealed off by adhesion to a neighbouring viscus, usually the under surface of the liver. The firmness with which the adherent surfaces were applied to each other, and the difficulty in separating them to suture the perforation, suggested that this was in fact unnecessary. When a similar case occurred later, therefore, I left the sealed-off perforation undisturbed without any untoward sequelæ, but it was obvious that I had performed a useless operation, having neither drained the peritoneal cavity nor sutured the perforation.

I collected 8 cases of this nature and found that the factor common to them all was that the patient's last meal had been eaten some time before the perforation—i.e., the stomach was relatively empty at the time. Consequently, not without trepidation, I tried to reproduce this condition in early cases by substituting gastric aspiration for operation, relying on the peritoneum to deal with the fluid that had already escaped, and on local adhesion to seal off the dried-up perforation.

The results were satisfactory beyond my expectation. Since January, 1945, 28 consecutive cases have been treated in this way; 24 patients made an uneventful recovery, 3 died from causes unconnected with the treatment, and 1 died who might have been saved by immediate operation, if I had had the experience at the time to recognise the limits of applicability of the conservative method. With the experience that has been gained and is now recorded, such an error in the selection of treatment should be avoidable in future.

CLINICAL PROCEDURE

At King George Hospital, Ilford, when a case of perforated ulcer is received, the decision whether to apply conservative treatment or to operate is made in the receiving-room (see below). If conservative treatment is adopted, the patient receives morphine gr. $^1/_4$ intravenously, repeated if necessary, and sucks a lozenge of amethocaine gr. 1. When thereby his pain and anxiety are dulled and his throat has become insensitive, his stomach is emptied with a large stomach-tube attached to a Senoran's gastric-suction bottle. The tube is then withdrawn, and the patient is sent to the ward. When he has been made as comfortable as possible in bed, a small stomach-tube is passed through the nose and fixed in position, and the stomach is aspirated at half-hour intervals with a 20 c.cm. syringe. The quantity of fluid withdrawn plus three pints in the twenty-four hours is administered rectally, subcutaneously, or intravenously. Small sips can be given, provided they are aspirated out again at once; otherwise nothing is allowed by mouth for the first day. Chemotherapeutic agents may be given by injection if necessary.

The treatment is continued during the second twenty-four hours, but now hourly aspirations are followed by drinks of 1 oz. of water. A mixture of milk and water is substituted on the third day, and the tube is removed when the fluid chart indicates that the amount taken by mouth is passing into the intestine and is not collecting in the stomach. Subsequent treatment is exactly as for acute non-perforated ulcer, with graduated diet, oil, powder, &c.

On this régime pain diminishes rapidly, and the patient is generally comfortable within twelve hours or so. It is interesting to observe the disappearance of the signs progressively from the left lower abdomen towards the epigastrium and right flank, where tenderness may persist for some days. The indwelling tube is a source of discomfort to the patient, but is usually gladly borne when it is explained that the alternative is an operation.

There is usually very little constitutional disturbance, and the pulse-rate remains about normal. Ileus may be expected in the not-so-early perforation, for which it may be necessary to continue the aspiration longer than usual. The limiting factor in the selection of cases is implied in this consideration and will be discussed further. If proper judgment has been exercised, a serious ileus should not develop.

The treatment throws little more strain on the nurses than if the patient had been operated on, but it does require from them an appreciation of the fickleness of stomach-tubes. A dry aspiration should never be accepted as evidence of an empty stomach, unless a small drink by mouth can be immediately withdrawn through the tube.

CASE-RECORDS

The case-records include only unequivocal perforations with full-scale rigidity and tenderness, some being confirmed by the radiological demonstration of gas under

---

* Read before the Society of British Gastro-Enterologists, November, 1945.

Nutrition Society

The society is holding a conference on The Work and Aims of the Food and Agriculture Organisation on Saturday, Sept. 21, at 10.30 A.M., at the London School of Hygiene, Keppel Street, London, W.C.1. The speakers will include Sir John Orr, F.R.S., director-general of F.A.O.; Mr. D. Lubbock; Dr. P. Lamartine Yates; Dr. W. R. Aykroyd; and Miss E. Fautz.

Medical Society of the L.C.C.

There will be a clinical meeting of the society on Thursday, Oct. 3, at 3 P.M., at Dulwich Hospital, S.E.22, when the staffs of Dulwich and St. Olave's Hospitals will demonstrate cases.

Association of Industrial Medical Officers

The annual general meeting of the association will be held at the London School of Hygiene, Keppel Street, W.C.1, on Friday, Oct. 18th, at 5 P.M., and will be followed by a dinner at 7.30 P.M. On Saturday, the 19th, at 10.30 A.M., Dr. Donald Hunter and Dr. R. S. F. Schilling will speak on Industrial Medicine in the U.S.A.

St. Thomas's Hospital

Dr. A. L. Crockford has been appointed secretary of the medical school in succession to Dr. R. J. C. Thompson, who has resigned.

Brazilian Honour

The Brazilian order of the Southern Cross has been conferred on Sir Alexander Fleming, F.R.S., who presided over the Inter-American medical congress which met in Rio de Janeiro this month.

Return to Practice

The Central Medical War Committee announces that Dr. Kenneth O. Black, 27, Weymouth Street, W.1 (Langham 3336), has resumed civilian practice.

DR. E. H. VAN SOMEREN.—A footnote in a recent boo memoirs states that Dr. van Someren, who practised Venice from 1898 to 1913, suffered from melancholia committed suicide in Venice. His obituary notices (see *La* 1913, i, 793; *Brit. med. J.* 1913, i, 589) make it clear t he died at Syracuse after a short illness at the age of 41; *was a diabetic and died in coma after contracting* influen

CASE 13.—Man, aged 67, with history of chronic bronchitis, angina of effort, 10 years' history of dyspepsia; ulcer perforated for 3 hours, 9 hours after a meal. Pain-free in 24 hours. Tenderness gone in 3 days. An ill man on admission. Doubtful if he would have survived operation. Steady recovery on aspiration.

CASE 14.—Man, aged 47, with 18 months' history of duodenal ulcer; perforated for 2 hours, 4 hours after a meal. Pain lasted 2 days on aspiration. Tenderness in right flank persisted 6 days—subsided. Steady recovery, though slower than usual.

CASE 15.—Man, admitted moribund, aged 65, with chronic phthisis, chronic retention of urine, repeated melæna, 12 months' history of failing health, 10 years' history of dyspepsia; ulcer perforated for 24 hours.

It was intended to operate on this patient if he could be improved sufficiently. Aspirated 11 hours until death. At necropsy two ulcers were found, one on middle of lesser curve, and one prepyloric, which had recently perforated and been sealed off by liver. Thin peritoneal fluid, not cultured. Tuberculous lungs, degenerate myocardium.

Case 16.—Man, aged 50, with 10 years' history of dyspepsia; perforated $2\frac{1}{2}$ hours. Patient had drunk two pints of beer to relieve pain. Pulse-rate 120. Uncontrollably restless, fought the nurses, pulled out his stomach-tube, drank his mouth-wash. Tenderness diminished under treatment, but abdomen became distended and remained so. After enema on third day patient had another sudden pain and condition deteriorated. Re-perforation diagnosed.

Operation (C. A.) in extremis. Suprapubic drainage of pouch of pus. Patient died 3 hours later. Necropsy showed anterior duodenal ulcer, not adherent. A ring of fibrin round it and on the under surface of the liver suggested that the two surfaces were adherent at one time and had separated again. Dilated intestines. Loculations of pus in various parts of abdomen. Death from peritonitis and ileus.

I should have operated on this man in view of the beer he had drunk and his resistance to the treatment.

CASE 17.—Man, aged 26, with 3 years' history of duodenal ulcer; perforated for 4 hours, 2 hours after a meal. General tenderness persisted 48 hours before resolving. Pulse-rate 112, slowly decreased. Residual tenderness in right flank subsided after 6 days. Rather delayed resolution followed by steady recovery.

CASE 18.—Man, aged 41, with 12 years' history of duodenal ulcer; ulcer perforated 2 hours before admission, while patient was at luncheon. General pain disappeared in 4 hours. Tenderness in right side lasted 24 hours. Uninterrupted recovery.

CASE 19.—Man, aged 32, with 4 years' history of duodenal ulcer; perforated for $1\frac{1}{2}$ hours, 3 hours after a meal. Pain gone in 24 hours, tenderness gone in 48 hours. Uninterrupted recovery.

CASE 20.—Man, aged 46, with 16 years' history of duodenal ulcer; perforated 6 hours. Pain subsided in 24 hours, tenderness gone in 4 days. Uninterrupted recovery.

CASE 21.—Man, aged 63, with hyperpiesis, dyspnœa, and cyanosis, and 2 years' history of dyspepsia; perforated $4\frac{1}{2}$ hours. Pain subsided in 3 days. Patient nearly died of heart-failure in first 3 days. Diagnosis of perforation proved by gas under right dome of diaphragm; patient could not have survived operation.

CASE 22.—Man, aged 65, with chronic bronchitis, dyspnœa, 30 years' history of duodenal ulcer; perforated 2 hours. Tenderness subsided in 3 days. Uninterrupted recovery.

CASE 23.—Man, aged 28, with no history of previous dyspepsia; perforated for 1 hour, 4 hours after a meal. Pain subsided in 6 hours, tenderness gone in 2 days. Uninterrupted recovery. Radiography showed duodenal ulcer.

CASE 24.—Man, aged 23, with 7 years' history of duodenal ulcer; perforated for 5 hours, 1 hour after a meal. Smooth rapid subsidence of pain. Uninterrupted recovery.

CASE 25.—Man, aged 31, with 10 years' history of duodenal ulcer; perforated for 1 hour, $\frac{1}{2}$ hour after tea. Pain subsided in 2 days. Tenderness persisted 3 days, with slight degree of ileus. Slow but steady recovery.

CASE 26.—Man, aged 36, with 16 years' history of duodenal ulcer; perforated for 3 hours, 6 hours after a meal. Pain gone in 6 hours, no tenderness after 3 days. Uneventful recovery.

CASE 27.—Man, aged 50, with 10 years' history of dyspepsia; perforated while visiting wife in hospital. Gas below diaphragm. Pain gone in 24 hours, no tenderness after 4 days. Uneventful recovery.

CASE 28.—Man, aged 65, with 20 years' history of dyspepsia; perforated 8 hours, 1 hour after a meal. Low vitality; cold and collapsed. Pain subsided in 12 hours, tenderness in 3 days. Uneventful recovery. Gastroscopy on 10th day showed a healing lesser-curve ulcer at the incisura. Doubtful if he would have survived operation.

MORTALITY AND MORBIDITY

Several of the patients were very poor surgical risks indeed and would have stood little chance with operation. Cases 5, 13, 15, 21, and probably 22 and 28 may be placed in this category without postulating any postoperative complications in the others.

Mr. Ian Soutar, my house-surgeon, investigated the hospital results under the old régime to compare with those we were obtaining, and to sustain our wavering morale after the tragedy of case 16. He found that in the preceding five-year period there were 77 perforated ulcers of less than twenty-four hours' duration, the average time being five and a half hours. Of these patients 14 died, a case-mortality of 18%. More than half the deaths were due to heart-failure or to pneumonia, an interesting comment on the bad-risk cases that were *not* operated on in my series. The postoperative morbidity-rate *among the survivors* was 46%, half of these being from pulmonary disease, and a quarter being associated with wound infection, breakdown, or subsequent hernia. It is obvious that there is a great deal to be gained by not operating if this can be achieved.

The 24 patients who recovered left hospital in 2–4 weeks. If it be conceded that the pulmonary embolus, the intestinal obstruction, and the moribund patient may be excluded from consideration of the mortality incurred by the conservative method of treatment, the result is 1 death in 25 cases. As a first series, these figures are promising, and they may be improved by further experience if a repetition of case 16 can be avoided.

DISCUSSION

If these early results are confirmed by further experience, it will seem that, in a district where the medical organisation is good, most patients with perforated ulcer admitted early to hospital need not be submitted to operation. Surgical intervention should be reserved for late cases, patients with pyloric stenosis and gastric dilatation, and those who have ingested a large quantity of fluid just before or after the perforation.

For sparsely populated districts, ships at sea, or any case where trained surgical help is not immediately available, the treatment described above, or a modification of it, may be given by a general practitioner or a nurse, or on board ship possibly by an untrained person, if a stomach-tube and syringe are available. Gastric aspiration should certainly be used in any case of perforation that has to wait long for a surgeon.

In this series all the perforations except two were duodenal; it remains to be seen whether gastric perforations behave similarly.

SUMMARY

Early perforations will seal themselves if the stomach is emptied and kept empty by aspiration.

Gastric contents in the peritoneal cavity will be sterilised and absorbed if the leakage is not gross and the contamination is not repeated.

Of a consecutive series of 28 perforations treated by gastric aspiration instead of operation, 24 patients recovered. Of the 4 deaths, 3 were not related to the conservative method of treatment.

It is suggested that the technique described is worthy of extended trial in early cases, operation being reserved the diaphragm. Three cases of doubtful perforation or limited leakage from an ulcer that occurred during the period of the experiment are not included in the list. There was one case of mistaken diagnosis during this time: a man, aged 56, subject to dyspepsia, who had had a sudden continuing pain four hours previously. There was generalised tenderness and rigidity of the abdomen, and he was treated by aspiration on a diagnosis of perforated ulcer. Persisting abdominal signs and a steady rise in pulse-rate, however, led to operation on the second day, when a tense gall-bladder was found and treated successfully by cholecystostomy. Two perforations in the series (case 6 and case 9) were also subjected to operation on the second day because of persisting generalised abdominal tenderness. In each of these the perforation was found to be sealed, but collections of sterile fluid in the pelvis and right flank were successfully drained. It may or may not have been necessary to do this, but the point to be made from these cases and that of the acute cholecystitis is that, if an expectant attitude is maintained in the management of the patients, no harm need result from the delay in operation.

In the early cases of the series one was, naturally perhaps, too ready to interfere and perform an intercurrent operation. Thus in case 3 one of my assistants inserted a suprapubic drainage-tube, which unfortunately gave rise to a fatal mechanical obstruction of the small gut in the pelvis. Another patient died from a pulmonary embolus on the fourth day of conservative treatment (case 10). Necropsy showed a sealed perforation, and a collection of sterile fluid in the right flank, besides the fatal clot. A third fatality was a man, aged 65, admitted twenty-four hours after perforating, too ill to be operated on (case 15). He was treated by aspiration for eleven hours in the vain hope that he would recover sufficiently for operation. Necropsy showed a sealed lesser-curve ulcer. None of these deaths was due to the treatment; indeed in case 3 the fatal issue must be attributed to the substitution of operation and drainage, though this was accidental.

In case 16 the method was a tragic failure. The patient, a huge unruly Irishman, had drunk two pints of beer after his perforation and was quite uncontrollable in the ward, drinking his mouth-wash and pulling out his stomach-tube. Obviously he should have been operated on, but this was put off till too late. He developed a loculated peritonitis and a severe ileus, which proved fatal on the fifth day. The case indicates the two chief contra-indications to the conservative method of treatment in an early case—inability of the patient to accept the treatment quietly; and the presumptive presence of large quantities of fluid (in this case beer) in the peritoneal cavity. The same consideration would apply when the stomach is dilated behind an obstruction, such as a stenosing ulcer, unless treatment has been prompt. Too much must not be asked of the peritoneal defence, and a limit must be recognised to the applicability of the treatment from this point of view. That this limit is fairly wide is suggested by the fact that the 28 cases were consecutive, though manifestly the sequence should have been interrupted by one case for operation.

CASE-REPORTS

CASE 1.—Man, aged 49; long history of duodenal ulcer; perforated 4 hours. Gastric aspiration for 10 hours. Pain and tenderness diminished. Assistant (P. H.) operated "to make sure perforation was really sealed." This was confirmed, and 10 oz. of sterile fluid was removed from peritoneal cavity. Recovery.

CASE 2.—Man, aged 31, with 6 years' history of duodenal ulcer; perforated 3 hours. Conservative treatment. Rigidity and tenderness subsided in 2 days. Patient went home in 3 weeks.

CASE 3.—Man, aged 57, with 3 years' history of duodenal ulcer; perforated 7 hours, 2 hours after a meal. Pain and tenderness subsided with 48 hours' aspiration, but abdome was rather distended. Pulse-rate 100–110.

Assistant (R. E. R.) operated on diagnosis of ileus after 2 da Suprapubic incision only; 2 oz. of sterile fluid removed. T inserted. Patient improved for 2 days, then distensi increased, and patient looked worse. Pulse-rate slowly Patient improved with Miller Abbott tube but continued

Operation (H. T.) after 7 days. Obstruction of small gut pelvis, dilated above and collapsed below an adherent kn where suprapubic tube had been. This was freed, but patien died 6 hours later.

At necropsy perforation was found to be securely sealed b liver. No intraperitoneal collection of fluid. Death fro toxæmia of intestinal obstruction due to the drainage-tube.

CASE 4.—Man, aged 52, with 10 years' history of duodena ulcer; perforated 3 hours, $^1/_2$ hour after a meal. Pain dis appeared after 12 hours' aspiration. Tenderness gone in 3 days Home in 4 weeks. Uneventful recovery without operation.

CASE 5.—Man, aged 61, with 15 years' history of duodenal ulcer; perforated 5 hours, soon after a meal. Poor physique, chronic bronchitis and emphysema. Dyspnœa on exertion. Enlarged prostate and chronic retention.

Pain and tenderness subsided with 48 hours' aspiration. Distension amounting to ileus persisted 5 days and the subsided. He recovered after some anxiety regarding th ileus. A very poor operation risk.

Twelve months later he was operated on for recurrence o symptoms: duodenal ulcer with membranous adhesions t liver. Gastro-enterostomy. Recovery.

CASE 6.—Man, aged 24, with 2 years' history of dyspepsia; perforated 2 hours, having had a meal 2 hours before. Patient improved with 18 hours' aspiration, but tenderness and rigidity remained diffuse. Operation (H. T.) therefore undertaken as precaution. Pyloric region adherent by fibrin to liver, not disturbed. Two ounces of peritoneal fluid—sterile. No drain. Patient did well as regards abdomen. Postoperative persistent fever and cough. Sputum containe tubercle bacilli. Radiography showed tuberculosis of left ape Patient was last heard of in a north Irish sanatorium, doi well.

CASE 7.—Man, aged 35, with 15 years' history of duoden ulcer; perforated 4 hours. Pain-free after 24 hours' aspiratio home in 2 weeks. Uneventful recovery.

CASE 8.—Man, aged 23, with 4 years' history of duoden ulcer; perforated $1^1/_2$ hours. Pain-free after 24 hours' aspir tion, abdomen soft in 48 hours. Uneventful recovery.

Subsequent recurrence of ulcer. Operation 4 months late Membranous adhesions between ulcerated duodenum an liver. Gastro-enterostomy. Recovery.

CASE 9.—Man, aged 45, with 4 years' history of duoden ulcer; perforated $3^1/_2$ hours, 1 hour after a meal. Patie improved after 28 hours' aspiration. Persistent gener though diminished rigidity and rising pulse-rate indicate operation (H. T.). Perforated duodenal ulcer found sealed o by liver. Peeled off and sutured. Collections of fluid i pelvis and right flank each drained with tube. Fluid steril

Patient did well. Operation was probably necessary t drain the fluid. Nothing was lost by 28 hours' delay. Flui was sterile, and ulcer sealed off.

CASE 10.—Man, aged 36, with 18 years' history of duodena ulcer; perforated $1^1/_2$ hours, 3 hours after a meal. Pai subsided in 6 hours. Tenderness persisted in right flank where a fullness indicated a fluid collection. This persiste 4 days, and local drainage was decided on. While bein prepared for operation, patient "went black" and die instantly.

At necropsy pulmonary artery and right auricle were foun filled with curled up ante-mortem clot from deep iliac an inferior caval veins. Death from pulmonary embolism Sterile collection of clear yellow fluid in right subphreni space. No peritonitis. Duodenal perforation well sealed of by liver.

CASE 11.—Man, aged 36, with 1 year's history of duodena ulcer; perforated for 2 hours, 1 hour after a meal. Pain-fre after 6 hours' aspiration. Tenderness gone in 2 days Uneventful recovery.

CASE 12.—Man, aged 26, with 2 months' history of dyspepsia perforated for 3 hours, $^1/_2$ hour after a meal. Pain-free afte 24 hours' aspiration. Tenderness in right flank persisted 4 days. Given penicillin as temperature was 102° F. Uneventful recovery. Radiography showed pylori ich had been exposed for $^{1}/_{2}$ hr. were brown, 1 hr. pink, d 2 hrs. red. A small area of the back exposed to an ultra-olet lamp on Jan. 14 gave a mild erythematous reaction ter a $^{1}/_{2}$-min. exposure at a distance of 2 ft.; an equally ond patient did not react to twice this dosage.

DESENSITISATION

Shock in penicillin therapy raises two questions: (1) hether a penicillin-sensitive patient in immediate need f injections of this drug, and having reacted with an naphylactic shock to a full injection dose, can be even emporarily desensitised with injections of small and increas-ng doses of penicillin at short intervals, given in the Bezredka tyle to prevent serum shock, so that full-dose therapeutic njections can be started without delay; and (2) whether patient can be desensitised by continuous administration small doses of penicillin for a longer period.

In an attempt to find an answer to the first question 100 nits of American sodium penicillin was injected under the kin with the intention of repeating the injection a short ime later, intramuscularly, with increasing doses. After 5 min. the patient, Bdr. A, experienced shock similar to that aused by the first injection of 15,000 units, but less intense nd less prolonged.

It is probable that starting with smaller doses we could eventually inject a full dose without incident, but such a technique would require a long time, many injections, and much discomfort for the patient. The problem of urgency could not be solved in this way. It remained to try the oral route used by Lieut.-Colonel C. J. H. Little and Captain G. Lumb, of the Central Pathological Laboratory, M.E. Their communication (Little and Lumb 1945) was published after our experiment had started with Lieut.-Colonel Little's counsel.

Fifteen minutes before the administration of penicillin, 4 oz. of milk mixed with one teaspoonful of sodium bicarbonate was given to the patient to drink. Fifteen minutes later American sodium penicillin 15,000 units in 2 oz. of milk, beaten up with a raw egg and a little sugar added for flavour, was given by mouth.

On Feb. 23 the first dose of penicillin was given by mouth. After $1^{1}/_{2}$ hrs. the patient complained of a burning sensation on the face. About $2^{1}/_{2}$ hrs. after the dose the face became pink and later turned red. The redness gradually increased in intensity and spread down the neck, and a mild œdema of the cheeks and eyelids appeared. The colour of the face returned to normal 10 hours after the first dose, but the skin of his rt. ear was irritating and discharging; during this time the patient was in bed and out of the sun.

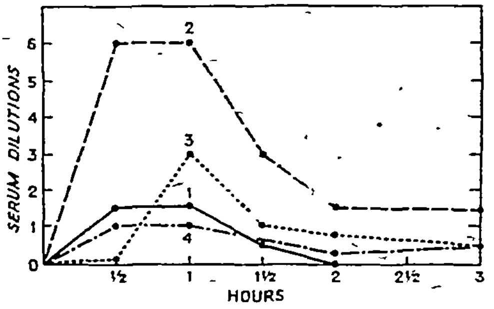
Next day, before having his second dose, the exuding dermatitis round the rt. ear had increased, and the redness of the whole face had reappeared, with more fine scaling as compared with his condition before the treatment began. The temperature and pulse-rate continued normal, and the general feeling good. The blood-count did not vary. On this 2nd day the patient had three doses orally of penicillin 15,000 units each at 3-hr. intervals. After each dose the same skin reactions were noticed as after the first.

Two days after the beginning of the desensitisation treatment, after four doses of 15,000 units in all, the face was very sore and the rash had extended gradually to the whole of his face. The area of exudative erythema increased, and there was much more scaling of the forehead and scalp. The temperature and pulse still remained normal, but the white-cell count rose to 16,000, with an unchanged differential count. In the next 24 hrs. the patient received eight doses of 15,000 units at 3-hr. intervals. He then, Feb. 26, complained of general malaise and was a little drowsy. The orbits, cheeks, ears, and lips were very swollen and red. The ears and the angles of his mouth were moist and fissured. The rest of the face, neck, scalp, and upper part of the sternum were papular, red, and scaling. The rt. foot, the one which was initially sprayed with penicillin, was now red and moist. The groins and scrotum were slightly red.

The daily doses were subsequently decreased to four given at 3-hr. intervals as before and then gradually again increased to eight as the symptoms subsided after ointments. On the 12th day of oral penicillin, March 3, the face, foot, and groin were dry and peeling. The patient then had eight doses of 15,000 units daily, without any other discomfort than a transient mild diarrhœa and frequent micturition. He was well enough to be up. The white-cell count gradually decreased to remain about 9000, with a normal differential count, until the completion of desensitisation Frequent analyses of the urine showed no abnormality.

On the 13th day of treatment, March 7, the patient received a subcutaneous injection of American penicillin 100 units without showing or feeling any reaction. The next day he received an intramuscular injection of 15,000 units without any general effect. There was a slight soreness and an increase of peeling on the face within 24 hrs. The 3-hourly full oral doses were continued for another 5 days and then stopped.

To estimate progress, penicillin spray with the 200-unit solution was again tried on the patient's face on March 13. After four applications the face became red, sore, and irritating. Although this reaction was much milder than before desensitisation was started, the skin was still sensitive. American penicillin 15,000 units was injected the next day, to see if such a dose could still be tolerated without anaphylactic shock. No ill effect was observed.



Bacteriostatic power of serum after oral administration of 15,000 units of penicillin. Curve 1: three days after start of desensitisation course. Curve 2: sixteen days later. Curve 3: after completion of desensitisation course. Curve 4: control.

Because of the partial state of skin desensitisation, oral penicillin was resumed at the rate of six daily doses of 15,000 units each, at 3-hr. intervals, so as not to disturb the patient in the night. This was continued for a further 11 days, without producing any general or skin symptoms. The desensitisation treatment had now lasted 30 days. The penicillin sprays on Bdr. A's face were repeated on March 16 and again were followed by puffiness of the eyelids, reddening of the cheeks and neck, and exudation on a very small area below the ear lobules.

On April 4 Bdr. A's face was sprayed with a solution containing 10 units of penicillin per c.cm. to ascertain the degree of remaining sensitivity of the skin after 30 days of desensitisation therapy. There was no reaction.

On April 9—i.e., 2 weeks after oral penicillin was stopped—his face was again sprayed with the 200-unit solution five times at 3-hr. intervals. Only a mild peeling and two small areas, about $^{1}/_{4}$ in. across, of dried-up exudate were noticed under each ear lobule the following morning; so small a reaction needed no treatment.

Walking in the sun for about 1 hr. next day provoked a peeling and slight redness of the ears and round the nose. Small squares of his back, exposed for $^{1}/_{2}$ hr., 1 hr., and 2 hrs. to the M.E. midday sun of April now gave the same reaction as on a normal blond control patient. Experimental exposures of small squares of his back to a quartz mercury-vapour lamp gave a very faint erythema after $^{1}/_{2}$-min. exposure. With continued exposures of his face to the sun the intensity of the actinic reaction gradually decreased, and on April 25 his face did not react to a 3-hr. exposure to the sun.

PENICILLIN CONTENT OF BLOOD-SERUM

Estimations of the penicillin content of the blood-serum were carried out for us. The first estimation was done in the blood drawn off 3 days after the beginning of the desensitisation treatment. Bdr. A had already had thirteen doses of 15,000 units each of penicillin. The estimation was repeated on 3 consecutive days (see figure, curve 1). Another estimation was made 16 days later, just before oral penicillin was stopped and 5 days after the patient had been tested with an intramuscular injection of 15,000 units, without producing anaphylactic shock (see figure, curve 2). The final estimation was made on April 13 after the last spray test on the face, 2 weeks after the end of oral treatment with penicillin; so, to make the conditions similar to those at the previous blood estimations, Bdr. A was given another nine doses of sodium penicillin, 15,000 units each, at 3-hr. intervals before the test (see figure, curve 3). The control (see figure, curve 4) was also given nine doses of sodium penicillin by mouth before the test.

These estimations were made for us by Lieut.-Colonel Little, R.A.M.C., on blood samples taken off $^{1}/_{2}$ hr., 1 hr., $1^{1}/_{2}$ hrs., 2 hrs., and 3 hrs. after oral administration of the for cases with gross flooding of the peritoneal cavity or late cases with established peritonitis.

The conservative method can be applied where surgical help is not available.

My thanks are due to the nursing staff of King George Hospital, Ilford, for their enthusiastic coöperation in this work; and to the resident surgical officers, Mr. R. E. Raynaud and Mr. Charles Allen, to the surgical registrar, Mr. Philip Hopkins, and to my house-surgeons, Mr. Ian Soutar and Mr. M. J. Whelan, on whose clinical judgment and reports I largely relied in the management of my cases.

SENSITIVITY TO PENICILLIN

ANAPHYLAXIS AND DESENSITISATION

W. J. O'DONOVAN
O.B.E., M.D. Lond.
LIEUT.-COLONEL R.A.M.C.
ADVISER IN DERMATOLOGY, MIDDLE EAST
PHYSICIAN, SKIN DEPARTMENT, LONDON HOSPITAL

I. KLORFAJN
M.D. Brux.
CIVILIAN MEDICAL PRACTITIONER ATTACHED TO A MILITARY HOSPITAL, MIDDLE EAST

ONLY a *few cases of skin sensitisation to penicillin* have been reported up to now in the medical journals available in the Middle East. Pyle and Rattner (1944) reported one case of epidermal sensitivity, and Binkley and Brockmole (1944) two cases. Silvers' case (1944) was in a chemist engaged in penicillin research. Criep (1944) reported a case of acquired allergy to penicillin after repeated intramuscular injections; generalised urticaria developed on the resumption of injections after an interval of ten days. Two patients who had been *treated with penicillin sprayings for skin affections* were admitted to a military hospital in the Middle East because their skin condition had worsened while under treatment. On examination they were found to be skin-sensitive to penicillin.

One of them, the subject of this report, was given an intramuscular injection of 15,000 Oxford units of penicillin and responded with a violent anaphylactic shock. He willingly submitted to experimental investigations and attempts to desensitise him with injections and later by oral administration of penicillin. The second patient was unwilling to undergo extensive experimental investigations, and will not be referred to further. *Importance is attached to the first case not only because desensitisation was successfully produced but also because it was done by the oral administration of penicillin.*

CASE-RECORD

Bombardier A, aged 30, gave no history of serious general diseases or accidents. He had always had a dry scalp and thin hair. About 14 years ago he had a mild rash in his groins for a few days. In England the summer sun regularly caused some dryness and peeling of the skin of his face. There was no history of asthma, hay-fever, eczema, or migraine in him or his relations, nor of any idiosyncrasy. He had spent six months in the M.E. before his admission to hospital. The sun in the M.E. did not affect his skin more than it used *to in England.* In June, 1944, some fissures appeared on the webs of the left foot with irritation. When these had been present for 3 weeks he showed them to the M.O. of his unit, who ordered three-hourly sprays of penicillin 200 units per c.cm.; this spraying was done five times daily for a week, without noticeable benefit. The skin subsequently cleared with bland ointments.

In October, 1944, he had an abscess over the left jaw, and penicillin sprays were again used for three days before incision. Two weeks later a rash broke out on the lower part of his face and on his left foot. He was admitted to the skin department of this hospital, where he was treated for two weeks as for seborrhœa with ointments of zinc oxide, castor oil, olive oil, and lime water, and the foot and face cleared. On Dec. 4, 1944, when on duty, his foot condition recurred and he was admitted to the *regimental sick-quarters* for ten days, where his foot was again sprayed five times daily. At the end of this time the condition of his foot had worsened and an eruption had broken out on his face.

CONDITION ON ADMISSION

On admission to the hospital on Dec. 14 he was noted t an active, intelligent, fair-haired, and slightly bald weighing 143 lb., B.P. 120/85 mm. Hg, with no visceral or nervous disease. The blood-count and urine normal. His face, forehead, and the front of his neck red. *There was a mild œdema of the* upper lip and ro nose and eyebrows, and a vivid small papulomacular rash his cheeks and the front of the neck. The dorsa of the toes and foot were red, slightly swollen, and shiny. No fu were found microscopically in scrapings from the affect skin areas. This history suggested an abnormal response his skin to penicillin *applied externally.*

PATCH TEST

A solution of penicillin containing 200 units per c c was applied on scarified and unscarified areas on his ba A fourfold pad of lint was soaked in penicillin and appl five times daily at 3-hr. intervals through a windowed occ ding square of 'Elastoplast.' As a control, on two ot areas the pads soaked in penicillin were left unchanged u taken off. The scarified area where the pad was chang three-hourly became red, mammillated, and moist—i.e., posit —after 21 hrs. All the others, changed or unchanged, beca *equally positive 48 hrs. from the first application.*

INTRADERMAL TESTS

An intradermal test was carried out with 0·2 c.cm. of sali containing 4 units of sodium penicillin. This produced a blush with a paler central weal after 3 hrs. The lo erythema persisted for over 2 weeks. The same amou of normal saline injected intradermally into the other a produced an erythema which disappeared after 48 hrs.

SPRAY TESTS

To confirm the diagnosis we sprayed the patient's fac and foot with a solution of *penicillin containing* 200 uni per c.cm. three-hourly. After five sprayings his face becam vividly red, swollen, and covered with an oozing fragi vesicular eruption. He complained of a severe local itchi and burning sensation. The foot reacted similarly but n so much.

ANAPHYLACTIC SHOCK

On the 17th the patient was given an intramuscular inje tion of 15,000 units of sodium penicillin (American man facture) in a surgical ward. Aseptic precautions were observe and the solution was taken from a rubber-capped bottle whi was in use also for other patients. Just before the injecti his pulse-rate was 64 per min., temperature 97·4° F, a white-cell count 8000 per c.mm. (polymorphs 71%, eosin phils 6%, lymphocytes 20%, and monocytes 3%). Fifte minutes after the gluteal injection his pulse-rate rose to 8 and he complained of a throbbing in his face; five minut later he complained of breathlessness, the pulse-rate becam very quick, and soon afterwards he was restless, very pal cold, and covered with a cold sweat, and then his bed w shaken by a violent rigor; his teeth chattered, his breathin was shallow, and his pulse thready and its rate uncountable he slowly recovered, being tired and weak for a couple of day His white-cell count about 3 hrs. after the shock was 10,20 per c.mm. (polymorphs 58%, eosinophils 3%, lymphocyte 29%, and monocytes 10%). His temperature remained norma

Six hours after this injection into the buttock, the patient' face swelled, reddened, and oozed all over. His right ey which was already showing mild conjunctivitis, became ve red and weeping, with some photophobia.

SENSITIVITY AFTER SHOCK

A penicillin patch test was again applied as before t determine whether this notable unexpected anaphylacti shock from the penicillin had desensitised him. The teste areas were irritating and pink—i.e., moderately positive *on the next day* and became markedly positive on the thir day. *On Jan. 17, 1945,* a limited area of his face was agai sprayed at 3-hr. intervals with the 200-unit solution penicillin. This produced a severe local reaction, the ski becoming red, swollen, and moist, a condition which laste eleven days.

ACTINIC REACTIONS

On Jan. 10, 1945, Bdr. A casually exposed himself to th M.E. winter sun. Approximately 2 hrs. later a moi red rash appeared behind his ears. As an experimen squares of his back were exposed to the sun on the afternoo of Jan. 11 through windowed black paper; next day the site

(d) *Dried stomach+vitamins:* 'Ventron' (P.D. CO.) two psules three times daily. Each capsule contains: ventrilin concentrate gr. 5 (equivalent to 1 g. original ventriculin); iamine 20 I.U.; riboflavine 5 Sherman units; and iron and dium citrate gr. 2 (0·13 g.).

(e) Details of the *protein hydrolysates* and the mode of ministration are mentioned in the text.

RESULTS

The results with the various forms of treatment used re summarised in the table.

ESPONSE OF 161 INFANT PELLAGRINS TO VARIOUS FORMS OF TREATMENT IN COMBINATION WITH A FULL DIET

Treatment	Total cases	Improved	Died
		%	%
Diet alone	10	6 (*60*)	4 (*40*)
Diet and vitamins	36	8 (*22*)	28 (*78*)
Liver extract (injection) ..	10	7 (*70*)	3 (*30*)
Oral liver extract + vitamins ..	15	4 (*27*)	11 (*73*)
Protein hydrolysate	20*	6 (*30*)	12 (*60*)
Dried stomach	50	47 (*94*)	3 (*6*)
Dried stomach + vitamins ..	20	13 (*65*)	7 (*35*)

* Two of these cases deteriorated so rapidly that treatment was changed.

Dried Stomach.—The case-mortality (6%) among the 50 cases receiving ventriculin is by far the lowest recorded for this malnutritional syndrome. In the small number of cases that die, even after ventriculin, the histological appearances of the livers differ in some important respects * from the most severely fatty livers of infants previously described (Gillman and Gillman 1945a, b, c, d).

Ventriculin breaks the vicious cycle operating in malnourished infants. This is evident from the sudden diuresis and the gradual disappearance of fat from the liver. Once this is achieved further treatment with ventriculin is unnecessary and the infant is capable of utilising effectively the constituents of a hospital diet.

Although gastric extracts have, thus far, proved successful in our hands, it is very likely that the vicious cycle may be broken by other methods, which remain to be discovered.

Dried Stomach and Vitamins.—The addition of vitamin concentrates and iron (thiamine and riboflavine) to ventriculin, as in the preparation ventron, significantly diminishes the effectiveness of the gastric extract, for the case-mortality among the ventron-treated cases was 35%. This chance finding was virtually forced on us by the fact that ventron, for a time, was the only form of gastric extract available to us.

Liver Extract by Injection.—In the absence of ventriculin, liver extract by injection is the treatment of choice. The case-mortality with this was 30% (see table).

Oral Liver Extract+Vitamins.—When liver extract is administered by mouth in combination with vitamins (thiamine, nicotinic acid, and cod-liver oil) the case-mortality rises to 73%. In a group of children treated with vitamins in conjunction with the hospital diet the case-mortality rose to 78%, the highest yet recorded by us for this syndrome. Most of these cases were treated by other physicians attending at the hospital. They were either unaware of the value of liver extracts and ventriculin or they were unable to obtain these products and therefore persisted with large doses of vitamin concentrates given orally and parenterally.

It may well be that the extremely high mortality was due to the massive doses of synthetic vitamins administered to these malnourished infants (up to 120 mg. thiamine and 300 mg. nicotinic acid daily, together with cod-liver oil). This we suspect from the fact that vitamins, added to ventriculin or liver extracts, were associated with an increased case-mortality (see table).

Protein Hydrolysates.—Our results with protein hydrolysates were most disappointing. Having read the numerous reports eulogising the value of these hydrolysates we had hoped that our cases might have responded to this new form of treatment.

The only reason for persisting with protein digests in the face of such discouraging results is that, from time to time, new preparations became available and it was thought that one of these might ultimately prove useful. Three different types of protein hydrolysates were used in the following manner:

(*a*) A local casein digest: 1 g. three times daily as a broth (8 cases).

(*b*) 'Pulvesco': a whale-meat digest kindly supplied by Dr. B. A. Dormer, chief tuberculosis officer for the Union. As directed, the children received one teaspoonful of this powder three times daily, together with 'Casec' feeds (5 cases).

(*c*) 'Pronutrin': an enzymatic digest of casein (7 cases). Our patients received the recommended dose—2 g. of pronutrin per kg. of body-weight per day. The dose was gradually increased, as recommended, to 4 g. per kg., which was given in 500–1000 c.cm. of 5% glucose saline. The total volume of fluid was administered by intragastric drip, only 50–100 c cm. being allowed to enter the stomach in an hour. This small amount of fluid was run in every alternate hour, day and night.

All the 8 patients treated with a locally prepared casein hydrolysate died within three to five days. Our experience with the last 3 cases of the series discouraged us from further trial of this product. These were admitted on the same day and were treated concurrently. For no apparent reason 2 developed temperatures of 105° F within 24 hours. No cause for this unusual pyrexia could be discovered at autopsy. We were led to suspect that the therapy, at least in part, was a contributing factor, especially as a similar instance of hyperpyrexia following the administration of protein hydrolysates has recently been described (Curreri et al. 1945).

Five cases were treated with pulvesco. Slow recovery was noted in 2 of these cases, while the remaining 3 died.

Pronutrin was also unsatisfactory in the 7 cases treated. Two cases, initially considered mild, both on clinical grounds and on the basis of the liver structure, deteriorated so rapidly that after four to six days the treatment was changed in the interest of the patients. Of the remaining 4, 1 recovered rapidly and the other 3 very slowly; 1 patient died.

The recent literature contains reports of the ineffectiveness of the majority of protein hydrolysates in the treatment of hypoproteinæmia in dogs (Madden et al. 1945). Severe hypoproteinæmia with œdema and anæmia has even been *produced* in pigs by feeding casein digests in a particular dietary setting (Cartwright et al. 1945). In the light of these findings the 60% case-mortality in our series of cases treated with protein digests is not difficult to understand.

DISCUSSION

It is clear from our findings that the administration of protein hydrolysates to infants with nutritional hypoproteinæmia, &c., fails to raise the plasma proteins, fails to resolve the œdema, and in fact appears to increase the mortality significantly above that observed in patients treated by graded increases in the diet alone. Only occasional cases appear to be capable of utilising these digests of casein. In the majority, the administration of these drugs appeared to aggravate the condition.

In this regard, the observations by Daft and collaborators (1938) are pertinent. These workers reported that "overloading" hypoproteinæmic dogs with plasma resulted in toxic symptoms with the excretion of greater drug. The slide-cell method was used for estimations given in curves 1 and 2, and the petri-dish cover-slip, substituted for the ordinary slide-cell, for the estimations given in curves 3 and 4. The test organism was the Oxford *Staph. aureus.* The following dilutions of serum were used: undiluted serum, the 1 : 2 solution, 1 : 4, and 1 : 8. When bacteriostasis was complete in one dilution and distinctly partial, as compared with the control, in the next highest, it was assumed that bacteriostasis would be complete in a dilution half-way between the two.

---

* Description of these differences is beyond the scope of this note but details will be made available in a monograph on malnutrition now in preparation.

DISCUSSION

The skin reactions to penicillin, however used, externally, intramuscularly, or orally, were limited to the areas initially treated with penicillin—i.e., face, neck, and foot. The rest of the skin remained clear throughout all the investigations and desensitisation treatment, except for the positive patch tests on the back and the intradermal test on the arm. The fact that the face reacted much less after the last test spray on April 9 with the 200-unit solution than after the previous one on March 27 with a solution of the same strength; although the patient had no further desensitisation treatment by the mouth, could perhaps be explained by abolition of the residual sensitivity of the skin of the face by the two sprayings before the last one—i.e., the antepenultimate with the 200 units per c.cm., and the penultimate with the 10 units on April 4.

Our aim in this case was primarily the desensitisation of the allergic patient, yet this record may perhaps contribute a little to the question of absorbability and therapeutic effectiveness of penicillin when given by the mouth, a special research on which work has since been published (Little and Lumb 1945). We searched for but failed to find microscopically any fungi, although the foot lesions led us to suspect antecedent epidermophytosis. We could not obtain trichopytin vaccine to test this possibility. Jadassohn et al. (1937) thought there was a common antigen in all the fungi present besides the specific ones; but Feinberg (1944) found that persons clinically sensitive to penicillin spores did not give a positive skin reaction to the penicillin drug. This was confirmed by Criep (1944), whose patient with penicillin urticaria gave a negative result to a patch test with penicillin extract.

The curves shown in the accompanying figure can probably be explained on the assumption that the antibody and antigen interact to form a compound which is slowly eliminated from the body, a reaction which is reversible, leading to disintegration of this compound. Thus, the difference between curves 1 and 2, showing the penicillin content of the blood-serum in progressive stages of desensitisation three days and nineteen days respectively after the start of desensitisation treatment, can be explained in the following way. In curve 1, the sensitivity being still at its height, antigen-antibody linkage and consequent bacteriostatic neutrality of the compound in the serum are the predominant factors, the reversible reaction, the disintegration of the compound into its constituents, playing in this stage a secondary rôle only. Curve 2 represents the total amount of penicillin coming into circulation after absorption from the intestinal tract as well as from disintegration of the antigen-antibody compound.

Curve 3 represents the free penicillin content of the blood at a later stage, when there was still a very mild skin sensitivity after the treatment with penicillin had stopped 2 weeks previously. This curve shows no free penicillin present in the $^1/_2$-hr. specimen; it had been taken up by the remaining antibody-antigen; but, owing to the great dilution of this compound, and as the antibodies at that stage were less numerous, it immediately underwent disintegration, and the freed penicillin gave, with the penicillin absorbed from the intestines, the conspicuous peak shown in the 1-hr. specimen. This curve is so much above the level of curve 4 given by the control patient that this additional factor—i.e., the freeing of the penicillin adminis an hour previously—must be taken into consideration.

SUMMARY

The case is recorded of a patient who became sen to penicillin in the course of ordinary dermat treatment with penicillin spray.

Anaphylactic shock followed an intramuscular injectio of penicillin.

Oral administration of penicillin brought about com plete desensitisation, abolishing superficial skin hype sensitivity and the shock effects of parenteral penicillin

Actinic sensitivity developed and faded pari passu wit penicillin sensitivity.

An explanation is offered, in terms of antigen-antibod theory, of the differences found in the penicillin conten of the blood during desensitisation and in a control.

A grateful note must be made of the assistance give us in counsel and practice by Colonel M. T. Findlay A.M.S., and Major A. Kirshner, R.A.M.C., pathologist t the hospital.

TREATMENT OF INFANTILE PELLAGRA

ASSESSMENT OF THE VALUE OF PROTEIN HYDROLYSATES

THEODORE GILLMAN
M.B., M.Sc. Witwatersrand

JOSEPH GILLMAN
M.B., D.Sc. Witwatersran

From the Department of Anatomy, Medical School, Universit of the Witwatersrand, Johannesburg

IN previous publications we drew attention to th syndrome of malnutrition in African infants and children In its acute form this expresses itself as a characteristi dermatosis, with varying grades of œdema, hypoprotein æmia, steatorrhœa, or diarrhœa. The case-mortalit can be very high and this is related to the severity of th fatty change in the liver which appears essentially in th early stages of the disease. By carefully selecting com parable cases, on the criterion of the extent of the fatt change in the liver, it became possible, by serial biopsies to assess the value of different forms of therapy on th liver and on the course of the disease (Gillman an Gillman 1945a, b, c, d).

In our hands gastric extract ('Ventriculin,' P.D. Co. has thus far proved to be the most satisfactory form o treatment in this disease in which the case-mortalit may fluctuate between 40% and 60% over a number o years. This finding has since been confirmed by Trowel and Muwazi (1945) on a small series of cases.

The lack of constant supplies of gastric extract made i possible to treat only a limited number of cases at a tim While waiting for further supplies we were constrained t use other forms of therapy. As a consequence, groups of cases were treated intermittently in different ways over a period of three years. Protein hydrolysates only became available to us about nine months ago. The following is a résumé of the various therapeutic measure adopted in 161 infant pellagrins.

All cases received the standard dietaries recommende for infants and children according to their age an weight. Supplements were added as follows:

(*a*) *Vitamins:* Thiamine 60 mg.; nicotinic acid or amid 100 mg.; riboflavine 2 mg.; brewers' yeast 4 g.; 15,00 units vitamin A and 1500 units of vitamin D as fish-liver oil.

(*b*) *Liver extracts:* By mouth, liquid extract of liver (B.D.H By injection, 5 c.cm. crude liver extract (Lilly) intr muscularly twice daily.

(*c*) *Dried stomach:* Ventriculin 5 g. by mouth twice dail for four to six days.

corpora lutea were found. Correlation between the estimated ages of the corpora lutea and the endometria with the dates of operation and menstrual history showed that ovulation took place on the 10th or 11th day and the 6th day of the respective cycles.

CASE 1.—A multipara, aged 49, with menorrhagia. Hysterectomy performed on the 14th day of 26-day cycle; menses 4 days.

Findings.—(1) Hæmorrhagic, well-developed, cytologically normal corpus luteum in the left ovary (1·5 cm. × 1 cm.).

(2) The endometrium presented long tortuous closely packed glands, rather dilated and containing secretion. The columnar-cell nuclei were basal, and the cytoplasm contained secretory granules or vacuoles. Well-marked spiral arterioles were present; and, though the stroma was dense and spindle-celled, it was evident that a developed secretory stage was present (fig. 1).

In this case the corpus luteum was at least 3 or 4 days old, probably older, and ovulation must have taken place at the latest on the 10th or 11th day of the cycle.

CASE 2.—A 4-para, aged 27, with menorrhagia and pain in the right iliac fossa. Curettage and right salpingo-oöphorectomy performed on the 7th day of 28-day cycle; menses 4–5 days, heavy with clots.

Findings.—(1) A recently ruptured graafian follicle or young corpus luteum in the ovary (1·5 cm in diameter). The stigma or point of rupture was still visible. Microscopically, early infolding was present, with an early luteal-cell development from a hyperplastic granulosa-cell layer and theca interna (fig 2).

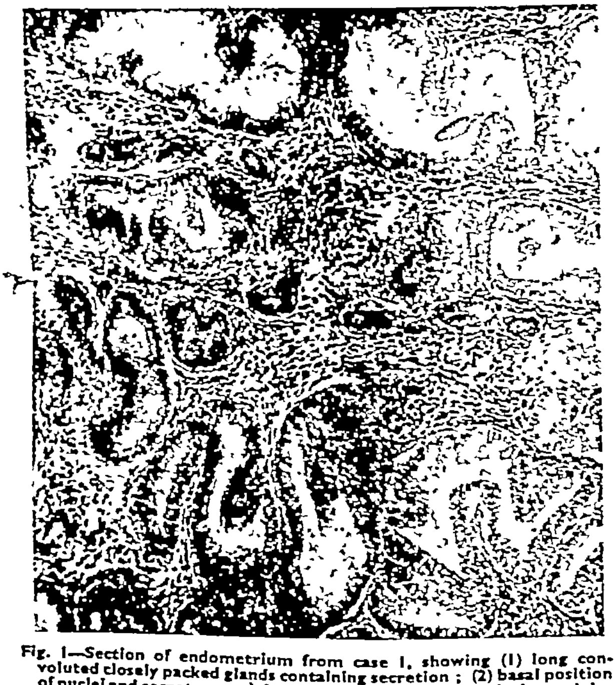

Fig. 1—Section of endometrium from case 1, showing (1) long convoluted closely packed glands containing secretion; (2) basal position of nuclei and secretory activity of cytoplasm; and (3) spiral arterioles in spindle-celled stroma.

(2) The curetting showed straight oval or round glands. Cytologically the nuclei were placed basally, but there was no more than a suspicion of secretory activity in the cytoplasm (fig. 3). The stroma was round-celled and oval-celled, containing developed spiral arterioles.

In this patient, the absence of secretory activity in the endometrium, together with a corpus luteum certainly no older than 24 hours, proves that ovulation took place on the 6th day of the cycle, or 36 hours after cessation of the menstrual flow.

Circumstantial evidence of early ovulation was found in eight other cases. Correlation of the date of biopsy and menstrual history was made with a conservative estimate of the time since the secretory stage was initiated.

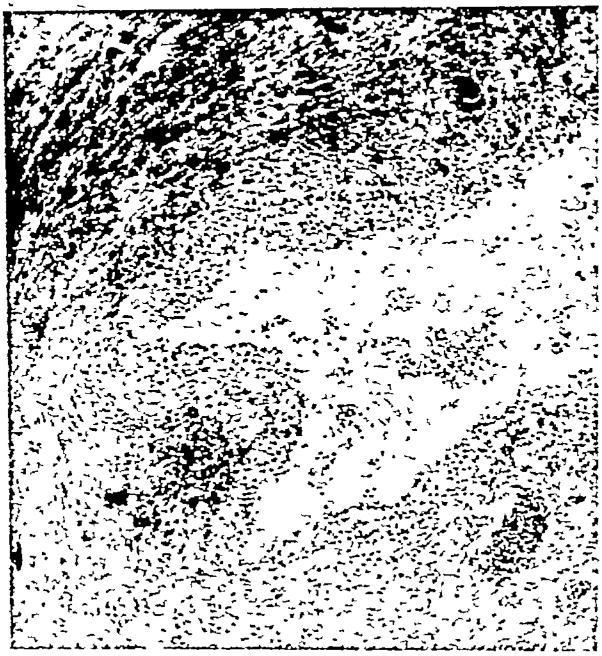

Fig. 2—Section of recently ruptured graafian follicle or very young corpus luteum from case 2.

Even assuming that the endometrial change to secretory activity takes place on the same day as follicular rupture, which is doubtful (see case 2), it seems that the ovulations had taken place between the 3rd and 11th days of the various cycles. The accompanying table shows how the day of ovulation was estimated. The age of the secretory stage was always estimated conservatively; hence the final column in the table is meant to give, not the actual day of ovulation, but the latest day of the cycle on which it could have occurred.

CASE 3.—An unmarried girl, aged 17, with dysmenorrhœa and menorrhagia. Curetted on 9th day of 28-day cycle; menses 6 days.

Findings.—Early secretory, partially dilated and tortuous glands, some of which contained secretion; œdematous round-celled stroma: a few spiral arterioles.

CASE 4.—An unmarried woman, aged 33, with recent hæmorrhage lasting 5 weeks. Curetted on 9th day of present cycle, her usual periodicity being 28 days.

Findings.—Secreting well-dilated tortuous glands, some more differentiated, showing "saw-teeth" appearance and containing secretion; basal nuclei in a columnar epithelium with secretory granules; stroma shows early pseudodecidual change, with numerous well-marked arterioles (fig. 4).

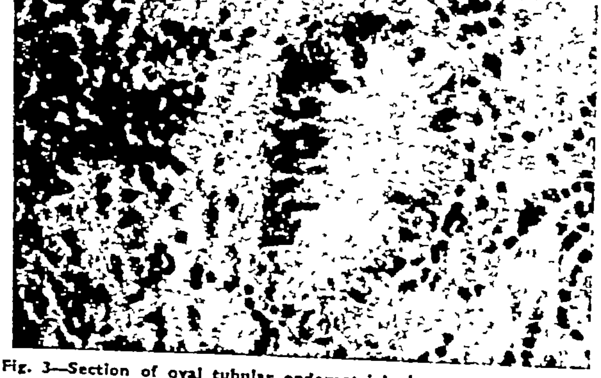

Fig. 3—Section of oval tubular endometrial gland, showing mitotic figures in two cells (from case 2).

quantities of nitrogen than could be accounted for by the amounts of protein in the administered plasma. It appears that "overloading" is a purely relative term. It may well be that our cases were incapable of utilising hydrolysed casein by virtue of the extensive liver damage present, and, more especially, because their metabolic apparatus could not adjust itself sufficiently rapidly to utilise these concentrates. If "overloading" were indeed responsible for the untoward results obtained then it is clear that criteria are needed for determining the dosage of protein hydrolysates to be administered to each case. Until such time as these criteria become available we feel that the administration of protein hydrolysates remains hazardous and is therefore contra-indicated.

Disease represents a particular homœostasis with its own peculiar regulatory mechanism which may have no counterpart in health. If the homœostasis in disease is altered by tampering with any one mechanism without understanding the basic character of the new homœostasis, then, quite clearly, such treatment can be expected to be attended by disaster.

Thus a disease, initiated by malnutrition and showing signs and symptoms regarded as vitamin deficiency, may be aggravated by the administration of vitamins. This is suggested from our results in the table. Similarly, the hypoproteinæmia observed in our cases may be an expression of a new homœostasis emerging in chronic malnutrition; administration of hydrolysates in these circumstances may also prove harmful. Treatment of a single symptom or sign of a disease in which there is widespread disorder of metabolism can often be irrational.

The success of ventriculin, in our opinion, is not due to the addition of a factor the absence of which from the diet originally caused the disease. Ventriculin is apparently able to cause such a radical alteration in the entire homœostasis that the malnourished infant can now take advantage of the essential constituents of a good diet.

SUMMARY

The results obtained with various forms of therapy in 161 cases of infantile pellagra are recorded.

The effectiveness of ventriculin in the treatment of this syndrome has been confirmed in 50 cases.

The addition of vitamin concentrates to ventriculin significantly detracts from its effectiveness as a therapeutic agent.

Vitamin concentrates in combination with liver extracts or ventriculin, or with a full diet, are contra-indicated in the treatment of this form of chronic malnutrition.

Since the administration of protein hydrolysates may result in toxic reactions, and very rarely promotes recovery, we consider this form of therapy hazardous. Until satisfactory criteria are established for determining the dosage in each case, such concentrates, in our opinion, are contra-indicated in the treatment of the acute episodes in the course of chronic malnutrition in African infants.

We wish to acknowledge our indebtedness to the Students Medical Council of the University of the Witwatersrand for a generous grant which made the continuance of this work possible. Thanks are also due to Dr. Wunsh and Dr. Kessel, resident medical officers, and to Sister Spikin for assistance in the wards.

EARLY OVULATION

SIMON SEVITT
M.D., M.Sc. Dubl., M.R.C.P.I., D.P.H.

THE theory of ovular menstruation supposes menstruation depends on ovulation and the formation the corpus luteum half-way through the normal menstru cycle of 24–35 days (Schroeder 1928). That menstruatio can take place without a preceding ovulation wa established for the macaque monkey by Corner an Allen (1929), Bartlemez (1933), Sharman (1944), Sevit (1943), Rock (1939), and others. Therefore there ar probably both ovulatory and non-ovulatory menstru cycles.

The question arises whether ovulation, when it take place, always does so between the 14th and the 16th days or can happen at any time during the normal cycle. Teacher (1935), correlating the ages of very young fertilised ova found accidentally at operation or a necropsy with the previous menstrual history, concludes that fertilisation, and therefore presumably ovulation, can take place on any day of the cycle except during menstruation. Evidence that ovulation can take place on any day of the first fortnight of the menstrual cycle, including the last days of menstruation, has been obtained by correlating the menstrual dates and date of operation with the state of the endometrial biopsy material and of the removed ovaries.

The development of the endometrium during the early part of the ovular menstrual cycle is under the influence of the œstrogenic hormones (follicular hormone, œstrin), secreted, at least in part, by the developing graafian follicle. The endometrial changes following ovulation and the formation of the corpus luteum are produced by the luteal hormone, progesterone. These later changes are characteristic histologically, and their finding in a uterine curetting or an endometrial "punch" from the fundus uteri can be taken as strong circumstantial evidence of the presence of a corpus luteum and therefore of a recent ovulation. When the ovaries are also examined and a corpus luteum is found, there can be no doubt that ovulation has taken place.

ESTIMATION OF DAY OF OVULATION

Case	Menstrual periodicity (days)	Duration of menses (days)	Day of biopsy*	Estimated age of secretory stage of endometrium (days)	Day of ovulation*
3	28	6	9	1–3	6–8
4	28	?	9	2–4	5–7
5	28	4–5	13	2–3	10–11
6	21	10	6	2	4
7	21	?	5	1–2	3–4
8	29	7	12	2	10
9	28	6	6	1	5

* Since start of previous menstruation.

The terminology of the endometrial phases is confused, and in this paper the simple classification of the histologist is used (synonyms in parentheses):

Stage 1: menstruation.
Stage 2: non-secretory, early and late (regenerative, follicular, interval).
Stage 3: secretory, early and late (luteal, progravid, premenstrual, post-ovulatory, differentiative).

In the menstrual and case histories that follow, the days are reckoned from the first day of the previous menstruation.

In these ten cases there is evidence that ovulation took place earlier than the mid-menstrual period. In two (cases 1 and 2) the ovaries were available and

EMPIRICAL TESTS OF LIVER FUNCTION

MONTAGUE MAIZELS *
M.D. Lond., F.R.C.P.
CLINICAL PATHOLOGIST, UNIVERSITY COLLEGE HOSPITAL

APART from tests of specific liver functions, such as the synthesis of hippuric acid, excretion of dyestuffs, &c., certain empirical tests have been devised which all depend mainly on excess of gamma globulin in serum (Kabat et al. 1943), though other minor factors may be concerned, since the various tests do not always give identical results. The object of the tests is threefold: (1) to distinguish between jaundice of parenchymatous origin and that due to obstruction of the bile-ducts; (2) to assist in the diagnosis of hepatitis without jaundice; and (3) to follow the course of toxic liver disease and aid in its prognosis. The present paper attempts to assess the relative value of some of these tests: Britton's (1945) modification of the Takata Ara tests; the cephalin-cholesterol flocculation test (Hanger 1939); the thymol turbidity test (Maclagan 1944); and the colloidal-gold test (Gray 1940).

Opinions about the value of these tests vary. Magath (1940) reports that, though the Takata Ara test was often positive in advanced cirrhosis, it was frequently negative in early cases; and, though many writers report negative findings in jaundice due to duct obstruction, others, including Magath, find a high proportion of positives. Further, it is generally agreed that this test may be positive in many conditions where the liver is not involved, including in one series 27% of mental cases (Ornstein 1937). It is therefore clear that the Takata Ara test fulfils none of the objects set out above, and this appears to be Magath's view.

The cephalin-cholesterol flocculation test is more satisfactory than the Takata Ara, though the reagent varies greatly in sensitivity and probably in composition. Thus, one sample may be unstable with the sera of normals and cases of toxic jaundice, and stable with bile-duct obstruction; another may be stable in normals and unstable in bile-duct obstruction (Pohle and Stewart 1941); and a third preparation may be stable in normals and in duct jaundice and unstable in toxic jaundice, in which case the typical flocculation as described by Hanger (1939) and by Nadler and Butler (1942) are obtained. The latter writers report that fresh cephalin-cholesterol preparations gave numerous false positives, and that typical results were only obtained with aged material. On the other hand, Mateer et al. (1943) found that fresh preparations were alone reliable. This variability constitutes the main drawback of the test, which has been of considerable value in the hands of some workers.

The thymol turbidity test, according to Maclagan (1944), gives a high proportion of positives in toxic hepatitis and is usually negative in obstruction of the bile-ducts. Unlike other tests it also permits of a quantitative assessment of the strength of the reaction and hence of prognosis and progress in cases of hepatitis. According to Maclagan, thymol turbidity roughly parallels the colloidal-gold test but is less likely to be positive in infections and in rheumatoid arthritis. Colloidal gold was not used in the present work but a colloidal suspension of Scharlach red, which is easier to prepare and probably gives similar results. Details of these tests are given in the appendix below. Responses to various tests are shown in tables I and II, together with the albumin-globulin ratios, which were often estimated in parallel.

RESULTS

Normals.—Here cephalin-cholesterol flocculation (C.C.), colloidal Scharlach red (C.R.), and thymol turbidity (T.T.) were almost always negative or at most weakly positive. Maclagan gives the range of T.T. as 0–4 units; in my series 96% of normals were less than 3 units, with one result of 4 and another of 5 units. The Takata Ara test (T.A.) gave so many false positives that according to these data it has no positive value; possibilities of its having a negative value will be considered later.

Parenchymatous Liver Damage.—This has been classified as follows. (1) Catarrhal jaundice, an acute infection sometimes proceeding to subacute hepatitis. (2) Subacute and chronic hepatitis, with little or no fever, but malaise, persistent moderate jaundice, and sometimes ascites; death may result in a few weeks or months, or the condition may proceed to cirrhosis. (3) Cirrhosis, which may obviously follow the preceding, or the stage of active hepatitis may be unobtrusive; cirrhosis then appears to be primary, with gastritis, hæmatemesis, or ascites as its salient features; jaundice, if present, is not severe.

Table I shows that in catarrhal jaundice positive findings are the rule, and the albumin-globulin (A./G.) ratio was less than 1·5 in 11 of 18 cases. In 4 cases there were negative or doubtful findings; these patients were already improving or began to improve during the fortnight which followed the test. In one case alone all

* In receipt of a grant from the Graham Research Fund.

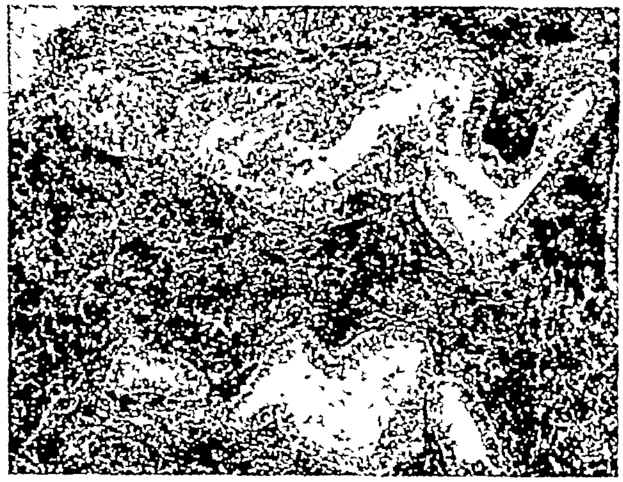

Fig. 4—Section of secreting endometrium, showing convoluted glands containing secretion (from case 4).

CASE 5.—A 3-para, aged 37, with excessive postmenstrual leucorrhœa. Piece from fundus removed on 13th day of 28-day cycle; menses 4–5 days.

Findings.—Glands mostly moderately dilated and somewhat tortuous, with eosinophil granular vacuolated cytoplasm and basal nuclei. Some are smaller and are round straight tubes not secreting. Stroma cells are in an early pseudodeciduous condition; spiral arterioles fairly numerous and well developed.

CASE 6.—A 2-para, aged 28, with menorrhagia and vaginal discharge. Piece from fundus removed on 6th day of 21-day cycle; menses 10 days—i.e., while still bleeding.

Findings.—Most glands convoluted and contain secretion; cytoplasm secreting and nuclei basal—i.e., early secretory stage. Some are non-secreting straight tubes. Stroma very œdematous, and well-developed spiral arterioles seen (fig. 5).

CASE 7.—A 3-para, aged 28, with menorrhagia. Piece from fundus removed on 5th day of 21-day cycle.

Findings.—Most of the glands were moderately dilated, some secreting and others not. Stroma œdematous in superficial layers, but nuclei densely stained and round: some thick-walled blood-vessels present, but most of the spiral arterioles thin-walled and mainly in the spongy layer.

CASE 8.—A primipara, aged 38, with metrorrhagia. Last period, heavy with clots, lasted 7 days. Piece from fundus removed on 12th day; menses started 17 days later.

Findings.—Early secretory endometrium, with moderately dilated and fairly tortuous glands; basally placed nuclei in secretory cytoplasm; stroma round-celled, with much œdema, thick-walled spiral arterioles mainly in deeper layers (fig. 6)

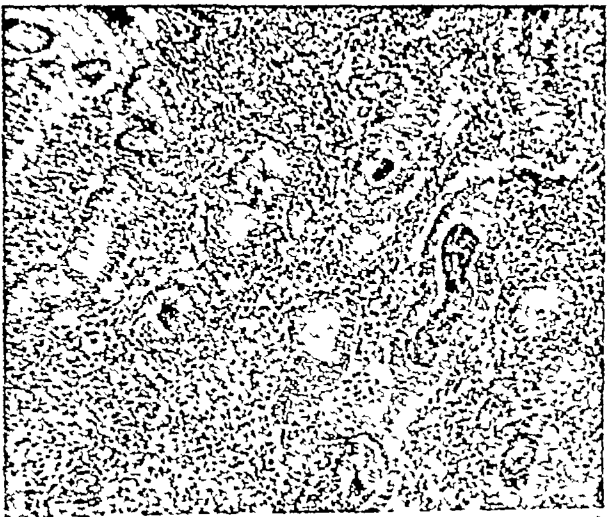

Fig. 5—Section of endometrium from case 6, showing most of the glands in early secretory phase.

CASE 9.—A 2-para, aged 30, with yellow discharge s miscarriage 2½ years ago. Cervical erosion present. Piece fr fundus removed on 6th day of 28-day cycle; menses 5 days—i.e., just ceased.

Findings.—Mostly straight tubular glands, but cytoplas shows the secretory vacuolated change with basal nucl in a columnar epithelium. Some glands rather dilated, othe show early convolution. Stroma presented no luteal effects. This is a very early secretory phase.

CASE 10.—A 4-para, aged 38, with vaginal discharge. Curetted on 14th day of 28-day cycle.

Findings.—Most glands are in the late secretory stage, some, however, are very convoluted but not secreting; stroma round-celled and œdematous; numerous spiral arterioles

DISCUSSION

The ten cases cited were selected from sixty-two case specimens of routine biopsy and operation material for which an accurate menstrual history and clinical details were available. It appears, therefore, that "premature" (or, more correctly, early) ovulation is not uncommon. In two cases ovulation occurred towards the end of the menstrual flow, when one would normally expect to find a reparative non-secretory phase of activity in the endometrium; but, instead, a secretory and therefore presumably luteal stage is seen. In the other cases ovulation took place on various days after cessation of the menstrual flow. It follows that there is no "safe" period in the first half of the menstrual cycle.

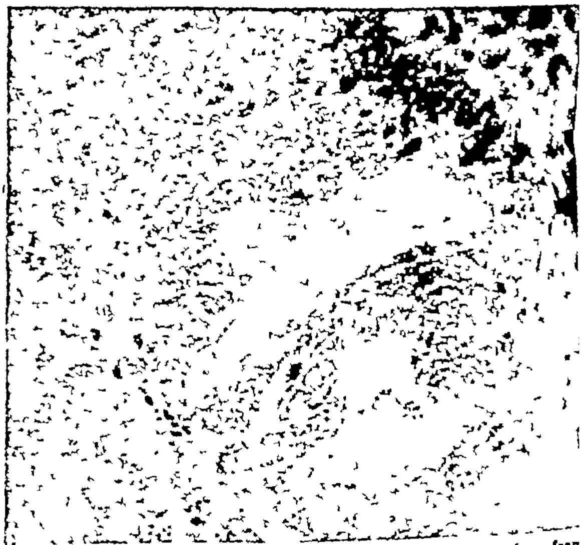

Fig. 6—Section of endometrial gland in early secretory phase from case 8, showing (1) swollen stroma cells and (2) mitoses in gland cells.

SUMMARY

Correlation between the menstrual history and day of operation of ten patients with the findings of a secretory and therefore presumably luteal endometrium during the first fourteen days of the menstrual cycle (and the finding of corpora lutea in two of these cases) supports the belief that ovulation can occur on any day of the first half of the cycle.

My thanks are due to Prof. O'Donel Browne and Dr N. Falkiner for supplying the operation and biopsy specimens; the late Mr. C. Hoppenkopper for preparing the sections; Mr. W. Kampf for the photomicrographs; and Prof. J. T. Wigham for his criticism and advice.

Sarcoids and Myelomata (table II, cases 8–14).—The liver was large in only 2 of 4 cases of sarcoid, and in no case was there clinical evidence of hepatic deficiency. But empirical tests were always positive and A./G. ratios low. In myelomatosis, on the other hand, though A./G. was still low, empirical tests were negative in 2 cases, whereas T.A. and C.R. were strongly positive in one.

Other Conditions (table I).—These were mainly arterial degeneration and non-malignant intestinal disorders; T.A. is often positive but hardly more so than in normals. Other tests were largely negative. Included in the series are 5 cases of hyperpiesia without nephritis, 1 each of starvation, pulmonary embolus with ascites, Milkman's disease, and polycythæmia vera; all these were negative. An apparent neurotic gave weak positives with T.A., C.C., and C.R. Not included in table I are 3 cases of ulcerative colitis, of which 2 gave negative tests and 1 gave consistently positive tests and had an A./G. ratio of 1/1. There were no cases of cardiac failure in this series, but Maclagan (1944) reports 3 weak positive T.T. and 5 positive colloidal-gold tests in 13 cases. He also reports 6 negatives and 1 weak positive T.T. in 7 cases of amyloidosis. It will thus be seen that there are various conditions in which empirical tests may be positive; the implications of this are considered later.

DISCUSSION

In my hands Britton's (1945) modification of the T.A. proved too sensitive, giving slight or moderate positives in non-hepatic conditions. Other modifications of the T.A. give fewer positives in non-hepatic lesions but are more often negative in frank hepatitis. On the whole, therefore, the T.A. was not considered a satisfactory test. C.R. was negative in about 80% of cases of jaundice due to obstruction of the ducts; C.C. gave 8% of strong and 8% of weak positives; and T.T. gave only 5% of weak positives. The A./G. ratio was usually low in hepatitis; a low ratio in duct obstruction usually indicated severe infection or extensive metastasis; it did not seem to be induced by the remote effect of blockage on liver-cells, even when this was prolonged. It therefore seems that in uncomplicated cases C.C., T.T., C.R., and the A./G. ratio will usually help to distinguish between jaundice of parenchymatous and duct origin. But the coexistence of such complications as cardiac failure, nephritis, rheumatoid arthritis, sarcoidosis, and lymphogranuloma

E.S.R. = Sedimentation of 100 mm. column in 60 minutes.

tests were consistently negative, though jaundice remained intense for nine weeks and then gradually faded. Pain was slight throughout, and the diagnosis remains obscure. On the whole it seems probable that, if signs have not begun to improve within a fortnight of a negative result being obtained, the jaundice is due to gross obstruction. In any case it will be apparent that the tests may sometimes be negative at a time when jaundice is still severe, and, on the other hand, that jaundice may improve while empirical tests remain unaltered or even intensify.

In subacute and chronic hepatitis, well-marked positive findings were invariable, and the A./G. ratio was below 1·2 in 10 of 11 cases. There were only 3 cases of cirrhosis, and C.C., T.T., and C.R. were negative in 2, while the less satisfactory T.A. was positive in all 3. Table I suggests that in parenchymatous jaundice C.C. and C.R. are the most satisfactory tests, with the much simpler T.T. a close runner-up. It is worthy of note that Maclagan (1944) reports 100% of positives for the colloidal-gold and T.T. in 13 cases of cirrhosis, though in a later paper (1945) he reports 2 negative cases. He classifies the parenchymatous group into infectious hepatitis and cirrhosis, and it is possible that a proportion of subacute cases is included with cirrhosis, in which case a high proportion of positives is to be expected. It would be unwise to draw conclusions from 3 cases, but at least the possibility exists that increase of gamma globulin together with the resulting positive empirical tests is associated with the activity of liver damage rather than with its extent.

Jaundice due to Obstruction of Bile-ducts or Hepatic Ducts.—In two-thirds of the cases T.A. was positive; it therefore has no positive value in differential diagnosis. On the other hand, it was positive in all cases of parenchymatous jaundice, and the tentative suggestion is made that a dead negative T.A. by Britton's method (1945) indicates duct obstruction, more especially when the associated jaundice does not clear within a fortnight of the test. With regard to the other tests, positive findings with one or other were recorded in 7 of 28 cases. Of 21 negatives one was a case of suppurative cholangitis; another had been severely jaundiced for eight weeks; while a third had been bronze-green for over a month. It follows that long-standing intense jaundice does not necessarily result in positive findings with C.C., T.T., and C.R. tests. The findings in the 7 positive cases are shown in table II (nos. 1–7). It will be seen that T.T. was low in all, and this suggests that a reading of more than 10 units is strongly against obstruction of the ducts. C.C. was positive in 3 and C.R. in 5 of the tabled cases, and all these had serious complications. Therefore, though negative tests do not exclude serious complications, positive findings suggest that such complications may be present. Of 8 cases of carcinoma of the liver with jaundice, T.A. was positive, and T.T. negative in all. Hence, T.A. is useless in distinguishing between carcinoma and hepatitis, whereas a positive T.T. makes carcinoma of the liver unlikely, and a negative T.T. indicates that hepatitis is probably absent. C.R. was positive in 4 cases, 2 being primary growths of the liver and 2 secondary; C.C. was positive in only 2 cases, both secondary.

The findings of other observers in cases of duct obstruction vary. Hanger (1939) finds that C.C. is negative or at most weakly positive in all cases. Nadler and Butler (1942), using an aged reagent, had 20 negatives and 7 weak positives, whereas Mateer et al. (1943) found that they could only rely on a relatively insensitive unripened preparation, and that even so half their cases of gallstones gave positive findings. So, too, Pohle and Stewart (1941) found, in 23 cases, 5 weak, 9 moderate, and 4 strong positives. With regard to T.T. and colloidal gold, Maclagan (1944) found only 3 slight positives. Once again it will be seen that Maclagan's simple test, though not infallible, is least likely to mislead in the differential diagnosis of jaundice. Hanger (1939) reports low A./G. ratios (less than 1·5) in 7 of 17 cases of duct obstruction; in the present series low ratios occurred in 10 of 26 cases.

In acholuric familial jaundice all tests were negative, and it seems clear that empirical tests will help to distinguish between hepatitis and other conditions causing jaundice, assuming that the obstructive jaundice is not associated with some independent disease which gives positive findings.

Nephritis.—It is clear from table I that T.A. gives many positives; C.R. was less affected, and very strong reactions, in contrast with what occurs in hepatitis, are not found. C.C. gave fewer positives than C.R., and T.T. again proved most satisfactory, giving only 1 weak positive in 20 cases. The results of the tests were not correlated with the A./G. ratio or blood-urea level.

Neoplasms without Jaundice.—These were mostly negative; 2 cases with metastases in the liver were positive with T.A. and C.R., and negative with T.T. and C.C. (table I).

Anæmias.—Five severe cases of microcytic anæmia were all negative. Most of the macrocytic anæmias gave positive T.A. tests, but only 3 gave positives with C.R. and C.C., and the reactions were weak. In these 3 cases macrocytosis was associated with hepatomegaly in one, with nocturnal hæmoglobinuria in another, and with an increase in the marrow plasma-cells (8%) in the third, and liver damage may well have existed in all (table II, cases 17–24). T.T. was negative in 7 cases, and weakly positive in 1 case. Maclagan (1944) reports 3 weak positive T.T.s, and 6 moderate or strong colloidal gold tests in 8 cases of pernicious anæmia.

Splenic Anæmia.—One case had normal hippuric-acid excretion; a second patient had undergone splenectomy, which had much decreased the incidence of hæmatemesis. Both cases gave positives with all four tests (table II, cases 15 and 16).

Poisons.—A case of early carcinoma of the parotid poisoned with sulphonamides (table II, case 25) had agranulocytosis and slight hæmolytic jaundice; except for T.T., all the tests were positive, and perhaps this case should have been included in the toxic-jaundice group; the same is probably true of case 26 receiving arsenicals for syphilis. In still another case receiving arsenicals, severe anæmia and agranulocytosis were present and the empirical tests were all negative.

Bacterial Infections.—Of 13 cases, 9 were positive to T.A., 2 to C.C., and 4 to C.R.; 1 was rather weakly positive to T.T. Maclagan (1944) gives 8 positive colloidal-gold tests in 12 cases, and 4 weak positive T.T.s in 8 cases. In table II cases 27–39 show that there is no correlation between empirical tests, A./G. ratio, and sedimentation-rate.

Rheumatoid Arthritis.—This group is interesting because of the frequency of positive findings recorded by Maclagan (1944). In the present series (table II, cases 40–44) T.A. was positive in 4, C.C. in 1, C.R. in 3, and T.T. weakly positive in 1 of 5 cases. Here too there was no correlation between these tests, A./G. ratio, and sedimentation-rate.

Tuberculosis.—Apart from the T.A., other tests were negative in this assorted group. In case 48 A./G. was very low, and the sedimentation-rate very high, but C.C., T.T., and C.R. were negative (table II, cases 52–57).

Lymph-gland Involvement (table II, cases 52–57).—Apart from T.A., empirical tests were negative or weakly positive in various conditions, including Hodgkin's disease and lymphogranuloma inguinale. Case 54, probably lymphogranuloma inguinale, gave positive tests. There were no cases of infectious mononucleosis in my series, but Maclagan (1944) reports 3 strong positive T.T. and colloidal-gold tests in 4 cases. It is interesting to note the frequency of low A./G. ratios in these glandular cases, due to increased globulin rather than to low albumin.

Sarcoids and Myelomata (table II, cases 8–14).—The liver was large in only 2 of 4 cases of sarcoid, and in no case was there clinical evidence of hepatic deficiency. But empirical tests were always positive and A./G. ratios low. In myelomatosis, on the other hand, though A./G. was still low, empirical tests were negative in 2 cases, whereas T.A. and C.R. were strongly positive in one.

Other Conditions (table I).—These were mainly arterial degeneration and non-malignant intestinal disorders; T.A. is often positive but hardly more so than in normals. Other tests were largely negative. Included in the series are 5 cases of hyperpiesia without nephritis, 1 each of starvation, pulmonary embolus with ascites, Milkman's disease, and polycythæmia vera; all these were negative. An apparent neurotic gave weak positives with T.A., C.C., and C.R. Not included in table I are 3 cases of ulcerative colitis, of which 2 gave negative tests and 1 gave consistently positive tests and had an A./G. ratio of 1/1. There were no cases of cardiac failure in this series, but Maclagan (1944) reports 3 weak positive T.T. and 5 positive colloidal-gold tests in 13 cases. He also reports 6 negatives and 1 weak positive T.T. in 7 cases of amyloidosis. It will thus be seen that there are various conditions in which empirical tests may be positive: the implications of this are considered later.

DISCUSSION

In my hands Britton's (1945) modification of the T.A. proved too sensitive, giving slight or moderate positives in non-hepatic conditions. Other modifications of the T.A. give fewer positives in non-hepatic lesions but are more often negative in frank hepatitis. On the whole, therefore, the T.A. was not considered a satisfactory test. C.R. was negative in about 80% of cases of jaundice due to obstruction of the ducts; C.C. gave 8% of strong and 8% of weak positives; and T.T. gave only 5% of weak positives. The A./G. ratio was usually low in hepatitis; a low ratio in duct obstruction usually indicated severe infection or extensive metastasis; it did not seem to be induced by the remote effect of blockage on liver-cells, even when this was prolonged. It therefore seems that in uncomplicated cases C.C., T.T., C.R., and the A./G. ratio will usually help to distinguish between jaundice of parenchymatous and duct origin. But the coexistence of such complications as *cardiac failure, nephritis*, rheumatoid arthritis, sarcoidosis, and lymphogranuloma

TABLE II—DETAILS OF EMPIRICAL TESTS ON VARIOUS CASES

Case group	Case	Clinical details	T.A.	C.C.	T.T. (units)	C.R.	A./G.	E.S.R. (mm. in 1 hr.)

E.S.R. = Sedimentation of 100 mm. column in 60 minutes.

tests were consistently negative, though jaundice remained intense for nine weeks and then gradually faded. Pain was slight throughout, and the diagnosis remains obscure. On the whole it seems probable that, if signs have not begun to improve within a fortnight of a negative result being obtained, the jaundice is due to gross obstruction. In any case it will be apparent that the tests may sometimes be negative at a time when jaundice is still severe, and, on the other hand, that jaundice may improve while empirical tests remain unaltered or even intensify.

In subacute and chronic hepatitis, well-marked positive findings were invariable, and the A./G. ratio was below 1·2 in 10 of 11 cases. There were only 3 cases of cirrhosis, and C.C., T.T., and C.R. were negative in 2, while the less satisfactory T.A. was positive in all 3. Table I suggests that in parenchymatous jaundice C.C. and C.R. are the most satisfactory tests, with the much simpler T.T. a close runner-up. It is worthy of note that Maclagan (1944) reports 100% of positives for the colloidal-gold and T.T. in 13 cases of cirrhosis, though in a later paper (1945) he reports 2 negative cases. He classifies the parenchymatous group into infectious hepatitis and cirrhosis, and it is possible that a proportion of subacute cases is included with cirrhosis, in which case a high proportion of positives is to be expected. It would be unwise to draw conclusions from 3 cases, but at least the possibility exists that increase of gamma globulin together with the resulting positive empirical tests is associated with the activity of liver damage rather than with its extent.

Jaundice due to Obstruction of Bile-ducts or Hepatic Ducts.—In two-thirds of the cases T.A. was positive; it therefore has no positive value in differential diagnosis. On the other hand, it was positive in all cases of parenchymatous jaundice, and the tentative suggestion is made that a dead negative T.A. by Britton's method (1945) indicates duct obstruction, more especially when the associated jaundice does not clear within a fortnight of the test. With regard to the other tests, positive findings with one or other were recorded in 7 of 28 cases. Of 21 negatives one was a case of suppurative cholangitis; another had been severely jaundiced for eight weeks; while a third had been bronze-green for over a month. It follows that long-standing intense jaundice does not necessarily result in positive findings with C.C., T.T., and C.R. tests. The findings in the 7 positive cases are shown in table II (nos. 1–7). It will be seen that T.T. was low in all, and this suggests that a reading of more than 10 units is strongly against obstruction of the ducts. C.C. was positive in 3 and C.R. in 5 of the tabled cases, and all these had serious complications. Therefore, though negative tests do not exclude serious complications, positive findings suggest that such complications may be present. Of 8 cases of carcinoma of the liver with jaundice, T.A. was positive, and T.T. negative in all. Hence, T.A. is useless in distinguishing between carcinoma and hepatitis, whereas a positive T.T. makes carcinoma of the liver unlikely, and a negative T.T. indicates that hepatitis is probably absent. C.R. was positive in 4 cases, 2 being primary growths of the liver and 2 secondary; C.C. was positive in only 2 cases, both secondary.

The findings of other observers in cases of duct obstruction vary. Hanger (1939) finds that C.C. is negative or at most weakly positive in all cases. Nadler and Butler (1942), using an aged reagent, had 20 negatives and 7 weak positives, whereas Mateer et al. (1943) found that they could only rely on a relatively insensitive unripened preparation, and that even so half their cases of gallstones gave positive findings. So, too, Pohle and Stewart (1941) found, in 23 cases, 5 weak, 9 moderate, and 4 strong positives. With regard to T.T. and colloidal gold, Maclagan (1944) found only 3 slight positives. Once again it will be seen that Maclagan's simple test, though not infallible, is least likely to mislead in the differential diagnosis of jaundice. Hanger (1939) reports low A./G. ratios (less than 1·5) in 7 of 17 cases of duct obstruction; in the present series low ratios occurred in 10 of 26 cases.

In acholuric familial jaundice all tests were negative, and it seems clear that empirical tests will help to distinguish between hepatitis and other conditions causing jaundice, assuming that the obstructive jaundice is not associated with some independent disease which gives positive findings.

Nephritis.—It is clear from table I that T.A. gives many positives; C.R. was less affected, and very strong reactions, in contrast with what occurs in hepatitis, are not found. C.C. gave fewer positives than C.R., and T.T. again proved most satisfactory, giving only 1 weak positive in 20 cases. The results of the tests were not correlated with the A./G. ratio or blood-urea level.

Neoplasms without Jaundice.—These were mostly negative; 2 cases with metastases in the liver were positive with T.A. and C.R., and negative with T.T. and C.C. (table I).

Anæmias.—Five severe cases of microcytic anæmia were all negative. Most of the macrocytic anæmias gave positive T.A. tests, but only 3 gave positives with C.R. and C.C., and the reactions were weak. In these 3 cases macrocytosis was associated with hepatomegaly in one, with nocturnal hæmoglobinuria in another, and with an increase in the marrow plasma-cells (8%) in the third, and liver damage may well have existed in all (table II, cases 17–24). T.T. was negative in 7 cases, and weakly positive in 1 case. Maclagan (1944) reports 3 weak positive T.T.s, and 6 moderate or strong colloidal-gold tests in 8 cases of pernicious anæmia.

Splenic Anæmia.—One case had normal hippuric-acid excretion; a second patient had undergone splenectomy, which had much decreased the incidence of hæmatemesis. Both cases gave positives with all four tests (table II, cases 15 and 16).

Poisons.—A case of early carcinoma of the parotid poisoned with sulphonamides (table II, case 25) had agranulocytosis and slight hæmolytic jaundice; except for T.T., all the tests were positive, and perhaps this case should have been included in the toxic-jaundice group; the same is probably true of case 26 receiving arsenicals for syphilis. In still another case receiving arsenicals, severe anæmia and agranulocytosis were present and the empirical tests were all negative.

Bacterial Infections.—Of 13 cases, 9 were positive to T.A., 2 to C.C., and 4 to C.R.; 1 was rather weakly positive to T.T. Maclagan (1944) gives 8 positive colloidal-gold tests in 12 cases, and 4 weak positive T.T.s in 8 cases. In table II cases 27–39 show that there is no correlation between empirical tests, A./G. ratio, and sedimentation-rate.

Rheumatoid Arthritis.—This group is interesting because of the frequency of positive findings recorded by Maclagan (1944). In the present series (table II, cases 40–44) T.A. was positive in 4, C.C. in 1, C.R. in 3, and T.T. weakly positive in 1 of 5 cases. Here too there was no correlation between these tests, A./G. ratio, and sedimentation-rate.

Tuberculosis.—Apart from the T.A., other tests were negative in this assorted group. In case 48 A./G. was very low, and the sedimentation-rate very high, but C.C., T.T., and C.R. were negative (table II, cases 52–57).

Lymph-gland Involvement (table II, cases 52–57).—Apart from T.A., empirical tests were negative or weakly positive in various conditions, including Hodgkin's disease and lymphogranuloma inguinale. Case 54, probably lymphogranuloma inguinale, gave positive tests. There were no cases of infectious mononucleosis in my series, but Maclagan (1944) reports 3 strong positive T.T. and colloidal-gold tests in 4 cases. It is interesting to note the frequency of low A./G. ratios in these glandular cases, due to increased globulin rather than to low albumin.

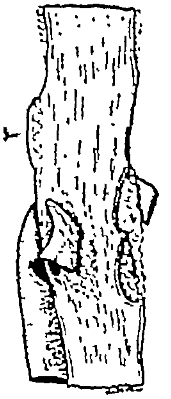
PERFORATION OF THE AORTA
BY SWALLOWED BONES

MAGNUS HAINES
M.D. Lond.
ASSISTANT PATHOLOGIST, WESTMINSTER HOSPITAL

THE anatomical relations and infective contents of the œsophagus make its perforation often fatal. Most of the cases, resulting from malignant ulceration, terminate with mediastinitis. However, when a foreign body becomes impacted in the œsophagus, usually at or just below the tracheal bifurcation, there are three possible sequelæ: (1) ulceration of the œsophagus, leading later to a cicatricial stricture; (2) perforation of the œsophagus, with subsequent mediastinitis and/or pyopneumothorax; and (3) perforation of the œsophagus and the aortic arch. The second of these sequelæ may precede the third. The history and post-mortem findings of two recent cases are reported here.

CASE-RECORDS

CASE 1.—A well-built man, aged 22, on leave from the Army, complained, after taking a mouthful of chicken on Dec. 27, that something had stuck in his throat. He ate no further dinner, and about 4 P.M. the same day sought advice at his local hospital. The pharynx and larynx showed no trace of a foreign body, and at the doctor's suggestion he swallowed a crust of bread without apparent difficulty. Four hours later he reported again at the same hospital, complaining of pain in the chest and of difficulty in breathing. Further examination revealed no abnormal physical signs, and the doctor advised him to return again in the morning if he felt no better. He lay in bed all next day (Dec. 28). Pain in the midline of the back, localised to a small area over the sixth thoracic vertebra, was first noted on this day, and he was "unable to swallow anything."



Sketch showing perforation of aorta by chicken bone (case 1). Œsophagus has been opened from behind.

He returned to duty on the 29th and "went sick." He was admitted to hospital that evening, when radiography of his chest showed no abnormal shadow. Next day, his temperature being 100° F, he was œsophagoscoped. After passing 23 cm. the instrument came upon an œdematous swelling. No foreign body was located, but it was considered unwise to attempt passing the instrument further, even if possible. A small hæmatoma was encountered 2 cm. proximal to the area of œdema.

A small hæmatemesis took place on Jan. 2, and a further 6 oz. of bright red blood was vomited at 12.30 A.M. on the 3rd. Three hours later the patient said he was going to be sick and tried to sit up, but fell back. The face blanched, severe air-hunger set in, and he died within 5 minutes.

At *necropsy* I found an irregular quadrilateral plate of chicken bone, whose sides measured approximately 2, 2, 3, and 3 cm., firmly lodged in the œsophagus, just below the bifurcation of the trachea (see figure). The anterior wall of the œsophagus was deeply congested and swollen. One angular corner of the bone had made a rent 1·5 cm. long in the anterior wall, but there was only slight inflammation in the circumœsophageal tissues at this point. Another sharper corner of the bone had pierced both the left posterolateral wall of the œsophagus and the contiguous aorta at the beginning of its descending portion. The tear in it was 8 mm. long, and there was almost no inflammation in the region. Clotted and fluid blood was found in the stomach and intestine. Apart from exsanguination, other organs presented no abnormal features.

CASE 2.—A housewife, aged 46, came to the hospital complaining that she had just swallowed a fish bone. Laryngoscopy and pharyngoscopy showed no foreign body. Radiography of a barium-cotton-wool swallow was negative. Two days later she was examined by the throat specialist, as the pain in the chest and back persisted. Again no foreign body was seen in the pharynx or larynx, and radiography again showed nothing abnormal.

Six days after swallowing the bone she vomited, for the first time, about half a pint of bright red partially clotted blood. She then fainted and was found on the floor in a collapsed state. On admission to hospital about two hours after the hæmatemesis she was pale and sweating. Examination by indirect laryngoscopy showed no foreign body. During the evening, and on four subsequent occasions during the next two days, she vomited more blood. On the day after admission œsophagoscopy was performed, but no foreign body or ulceration was discovered. After a final hæmorrhage (about 20 oz. vomited) she died next evening.

At *necropsy* a small area of œdema and congestion was found in the external aspect of the posterior wall of the œsophagus extending upwards from the level of the tracheal bifurcation. The mediastinal tissues immediately related to the under surface of the bifurcation and along the right bronchus showed early gangrene. Infection had tracked down interstitially from above. On opening the œsophagus from behind there was seen a recent oval ulcer ½ in. long and ¼ in. across, involving the entire thickness of the anterior wall of the œsophagus. It was about 4 in. below the level of the cricoid cartilage, though above the tracheal bifurcation. The ulcer communicated directly with the adjacent aorta, which had a tear in its wall ¼ in. long and situated just below the origin of the left subclavian artery. No foreign body could be found in the œsophagus, lungs, or mediastinum. A prolonged search was also made in the main branches of the aorta without finding any foreign body. Blood was found adhering to the ulcer and in the œsophagus. The rest of the alimentary tract contained large quantities of blood, both fresh and altered.

DISCUSSION

Several fatal cases have been reported, including those by Grey Turner (1910), Watson-Williams (1937), and Decoulx and Omez (1939). Many records can also be found of successful removal of a foreign body, in earlier years by œsophagotomy and nowadays by œsophagoscope. In the fatal cases the minute size of the foreign bodies, the length of time elapsing between the accident and the patients' coming under medical supervision, and the failure of radiography to demonstrate the foreign body seem to be important considerations. Grey Turner and Watson-Williams each report a case in which the bone was not found at the autopsy. In my case 1 radiography did not reveal the bone, and in case 2 the bone was never found. The time factor is very variable; commonly there is a 4–10 days' interval between the accident and a fatal aortic perforation. In Grey Turner's case the interval was 22 months.

The characteristic sign of injury to the aorta has been vomiting of blood, which occurs at short intervals but in increasing quantities until the final hæmorrhage. Watson-Williams believes that a prick perforation of the œsophagus leads to infection and necrosis of the arterial wall, and rupture finally ensues from intra-aortic pressure. This was a possible mechanism in one of his cases, where the fatal hæmorrhage closely followed the removal of the bone through the œsophagoscope. In my case 1 it seems that, owing to the size and sharp angle of the bone, pressure from the pulsating aorta aided penetration. There was no macroscopic inflammation in relation to this perforation. Even if the bone had been seen through the œsophagoscope on Dec. 30, the chances of removing it were almost nil. In case 2 it is considered that the bone may have been vomited or swallowed at any time after the aorta had been injured.

Decoulx and Omez report a very unusual case whose course was aggravated by a second accident. A miner, aged 37, continued at his work after swallowing a chicken bone. Ten days had gone by when, at work, he received a crush injury of the chest, which was followed by vomiting of blood. He died two days later from further hæmatemeses.

Diagnosis, without immediate endoscopy, presents many difficulties in these cases. In some, radiography will localise an opaque foreign body, but many foreign bodies are not dense enough to be visible—e.g., fish bones. That a patient with a fairly large object impacted in the inguinale might give confusing results. The complicating malady, however, is not likely to cause much difficulty since clinically it will be fairly evident. But this is not the case when jaundice due to duct obstruction is complicated by cholecystitis, subphrenic abscess, empyema, or poisoning by sulphonamides used in the treatment of infection. In all these conditions T.A., C.C., and C.R. may be strongly positive, though the high figures for T.T. encountered in hepatitis (10 units or more) are not likely to be met. There are no cases of hepatitis without jaundice in the present series, but other data suggest that empirical tests could not do more than lend support to a clinical diagnosis.

As regards choice of tests, in so far as T.T. is much easier than the others it is to be preferred, and it gives a simple and quick pointer to the nature of obscure jaundice and a quantitative measure of the degree and change of liver-cell damage. There seems to be no special advantage in using C.R., nor presumably in colloidal gold, though both are superior to T.A. The difficulty with the C.C. test lies in the preparation of a reagent of the right sensitivity. When this can be obtained, the test is probably superior to T.T., but in my experience two of three reagents prepared were too sensitive and rather unsatisfactory.

With regard to the origin of the empirical tests, cataphoretic studies (Kabat et al. 1943) show that these depend on increased gamma globulin. The cause of this increase is less clear. According to Gray and Barron (1943) the inability of the liver to form enough albumin is compensated by increased production of beta and gamma globulin or, if these fail, alpha globulin. It is, however, difficult to understand how, when albumin formation fails, the liver succeeds in producing greatly increased quantities of globulin. On the other hand, Bing (1940) has shown that hyperglobulinæmia occurs in many different bacterial, virus, and protozoal infections which all have in common much reticulo-endothelial or plasma-cell reaction. Another possible source of gamma globulin is the lymphocyte (Kass 1945).

In the present series increase of serum-globulin above the normal maximum of 3 g. per 100 c.cm. was observed in several instances, including 2 cases of rheumatoid arthritis with serum-globulins of 3·37 and 3·1; two cases of sarcoidosis with globulins of 4·22 and 3·96; 2 cases of Hodgkin's disease with globulins of 3·0 and 3·53; and 2 cases of lymphogranuloma with serum-globulins of 3·39 and 3·17 g. per 100 c.cm. In none of these cases was there evidence of liver involvement, and it seems likely that the site of globulin formation was elsewhere. This observation also applies to 2 cases of multiple myelomatosis (in one, albumin was 2·29 g. and globulin 8·36 g. per 100 c.cm.; in a second, albumin was 2·38 g. and globulin 9·92 g. per 100 c.cm.). In both, the figures suggest that albumin was reduced to a very low level to compensate for the excessive production of globulin. In 4 cases of hepatitis the A./G. ratios were 2·04/5·11, 3·46/4·34, 4·41/4·41, and 3·67/6·30. Here also it is perhaps possible that part at least of the increase in globulin is derived from an extrahepatic source and may compensate for deficient production of serum-albumin by the liver. If this compensation was osmotic, then, owing to its larger molecule, a relatively larger amount of globulin would be needed to compensate for the absence of a given weight of albumin. In these circumstances the total protein of a globulin-compensated serum would be greater than that of normal serum, a finding which is common in hepatitis and is illustrated in the 4 cases mentioned above, where the total serum-protein was 7·15, 7·80, 8·82, and 9·97 g. per 100 c.cm.

SUMMARY

The rating of several empirical liver tests in order of usefulness in the differential diagnosis of jaundice was: thymol turbidity, cephalin-cholesterol flocculation, colloidal Scharlach red (or colloidal gold), and Takata Ara.

If a case diagnosed as toxic jaundice gives negative empirical tests, it will probably begin to clear within a fortnight. Failure so to improve, with persistence of negative tests, suggests that the diagnosis is probably incorrect.

In obstruction of the hepatic ducts or bile-ducts the colloidal red is negative in 80% of cases and the cephalin-cholesterol flocculation in about 90%, whereas thymol turbidity rarely exceeds 10 units, even when the jaundice is long-standing and severe. When cases of duct obstruction give positive empirical tests, serious complications, such as metastases and infection, are commonly present, though extensive liver metastases may accompany negative tests.

Besides hepatitis, positive empirical tests may also be given by myelomatosis, sarcoidosis, certain types of adenitis, rheumatoid arthritis, sulphonamide poisoning, and infections with certain bacteria, protozoa, and viruses. If any of these maladies accompany simple duct obstruction, the positive tests may suggest that parenchymatous damage is present.

APPENDIX ON METHODS

Blood was collected in the morning, kept for three hours at 37° C, and then at room temperature. In the afternoon, serum was separated without hæmolysis, and the tests were put up immediately.

Takata Ara modified by Britton (1945).—Readings are as follows:

O = no change in any tube, or a cloud in tube 3, with or without a fine amorphous precipitate.
± = small gelatinous precipitate in tube 3 only.
+ = moderate or bulky precipitate in tube 3 only.
+ + = heavy flocculent precipitate in tube 3; some precipitation in tube 2.
+ + + = heavy precipitate in tubes 2 and 3. (Though exceptionally strong reactions sometimes occurred with precipitation in tube 1, no special record was made of these.)

Cephalin-cholesterol Flocculation (Hanger 1939).—Recorded as follows at 24 hours:

O = no change.
± = fine granularity without precipitation.
+ = granularity with some precipitation.
+ + = granularity with heavy precipitation.
+ + + = complete precipitation with clear supernatant fluid.

Thymol Turbidity (Maclagan 1944).—Recorded in table I as follows:

O = 0–4 arbitrary units.
± = 4–8 units.
+ = 8–12 units.
+ + = 12–20 units.
+ + + = 20–40 units.

Colloidal Scharlach Red.—A saturated solution of the dye in alcohol is kept at 37° C; 10 ml. of this in a clean conical flask and 50 ml. water in a second flask are warmed to about 55° C and the water quickly added to the dye solution. The mixture is then boiled first in the bath and then over gauze till the final volume is about 20 ml. The volume is then made up to 75 ml. and 0.35 ml. Evans blue (0·2%) is added. For use, 0·5 ml. of the reagent is added to 0·5 ml. of serum diluted to 1/2, 1/4, and 1/8 with saline (0·85%). Results are read next day. If the serum is icteric, an identical control series may be put up at the time of reading to facilitate identification of colour changes. In the case of sera, readings are as follows:

	Non-icteric sera		*Icteric sera*
O	= purple or violet	=	orange or dirty green.
±	= blue tinged with violet in 1 tube only	=	dirty green in 1 tube only
+	= sky blue in 1 tube only	=	bottle-green in 1 tube only

Sharp relief
with

Proctocaine
Local Anaesthetic-Analgesic
ALLEN & HANBURYS LTD. LONDON, W.1

In Muscular Rheumatism, Lumbago, Sciatica, Etc.

In lumbago, Proctocaine gives dramatic relief—from rigidity to painless mobility in a few minutes, so that the fibrositis subsides quickly. Lasting recovery from sciatica has followed two injections, each of 5 c.c. of Proctocaine, into the region of the nerve, a fortnight apart, the first being preceded by an induction anæsthetic. Two months' sciatica was relieved by 1 c.c.

œsophagus can swallow solids is undoubted, and this fact cannot be too strongly emphasised. Many years ago Grey Turner cited the cases of a woman who took her ordinary food for three days despite the presence of a plate of false teeth in her gullet, and that of a child who had remained well nourished although a halfpenny was lodged in the œsophagus for one year and ten months.

During the course of a lifetime every practitioner sees scores of patients who have swallowed various articles, and many of these complain of pain in the chest. It is generally believed that very few objects swallowed in this way become impacted, and consequently œsophagoscopy is not often undertaken. But Chevalier Jackson (1940) states that "in the College of Physicians of Philadelphia there are nearly 4000 objects, each o which has been removed from the air and food passag of patients at the bronchoscopic clinics of Philadelphi The cases reported here and others described in th literature may serve to show why we should become mor "œsophagoscope conscious."

My thanks are due to H.M. Coroners, North London an West London, for permission to publish the cases, and t Mr. E. Stanley Lee for his help in compiling the history in case 1

Reviews of Books

An Introduction to Clinical Neurology

GORDON HOLMES, M.D., F.R.S. Edinburgh: E. & S. Livingstone. Pp. 183. 12*s.* 6*d.*

THE distinctive feature of the British tradition in neurology is the intimate relationship between clinical neurology and neurophysiology. Everywhere clinical neurology is based upon neurophysiology, but nowhere else has neurophysiology been so much enriched by the work of clinicians. There is no more distinguished example of this than Dr. Gordon Holmes, whose work has contributed so much to our knowledge of the physiology of sensation, vision, and the cerebellum. Many, therefore, will welcome this book in which he makes available to a larger circle the teaching which generations of students at the National Hospital have valued and enjoyed. It is, as the title states, an introduction to clinical neurology, based upon the interpretation of neurological symptoms and signs in terms of anatomy and physiology. The main functional divisions of the nervous system are dealt with in turn, the motor system, muscle tone, convulsions, sensation, the reflexes, the visual system, speech, the sphincters, the autonomic nervous system, and the mental state, to mention the more important. The student beginning neurology will find here the necessary foundations of the subject, and the practising neurologist will enjoy the lucidity of the exposition.

The Surgical Teaching of Abdominal Operations

(4th ed.) J. L. SPIVACK, M.D., associate professor of surgery, University of Illinois. Springfield, Ill.: Charles C. Thomas. London: Baillière. Pp. 710. 55*s.*

THIS handsomely printed book has been considerably revised, yet remains an encyclopædia rather than an eclectic account of practical methods. Even so, there are omissions. Nine methods of gastropexy, an operation of doubtful value, are described, yet there is no account of the difficult dissection of the duodenum which is so often called for. Professor Spivack's ingenious methods of cholecyst-gastrostomy and the formation of an artificial anus are interesting. He is against aseptic methods of anastomosis for the stomach. The book will be read by experienced surgeons with much profit and entertainment.

Pediatric X-Ray Diagnosis

JOHN CAFFEY, A.B., M.D., associate professor of pediatrics, Columbia University, N.Y. Chicago: Year Book Publishers. London: H. K. Lewis. Pp. 838. 75*s.*

THIS is the first textbook in English on the use of X rays in the diagnosis of children's diseases and is an elaboration of Dr. Caffey's well-known section in Ross Golden's loose-leaf *System of Radiology*. The author was clearly a pædiatrician before becoming a radiologist, and while some of the finer points of radiological technique are missing, their loss is more than balanced by his excellent clinical judgment. In every section of this book the radiological appearances are assessed with the clinical and pathological findings, and where one preponderates suitable emphasis is laid on it. Rare diseases are but briefly mentioned and most of the text and illustrations deal with the common and important diagnostic problems. A striking commentary on the different values of X-ray diagnosis in children and adults is that the gastro-intestinal tract occupies only 60 pages while neurology gets 160, the bones 200, and the chest 200. The illustrations are well selected and enhanced by the addition of beautiful anatomical and pathological drawings. The book is the work of a practical man, demonstrating facts as he found them in over twenty years' experience in a children's hospital. It will be of great value to all radiologists, relatively few of whom have the opportunity to work in a large children's department. It should also prove a revelation to the many pædiatricians whose radiological outlook, in this country at least, has been limited by indifferent equipment.

Chemistry and Physiology of Hormones

Editor: FOREST RAY MOULTON. Washington: American Association for the Advancement of Science. Pp. 243.

THIS book, to quote the foreword, grew out of a research conference held at Gibson Island, Maryland, in 1943. There are 18 authors, workers in the fields in which they write. The policy has been to give résumés of the well-established findings on the various subjects, without excluding discussion of current work. Whilst the publication should be of value as a reference book for endocrinologists and teachers—there are some 1200 references—the more general reader, by intelligent selection, can read it with profit and pleasure. An index would have helped readers of both kinds. The 18 articles cover most of the known hormones and endocrine glands and the relationships between them; but some account of the synthetic hormones of the stilbœstrol type might well have been included. Our knowledge of the mode of action of insulin, conservatively estimated by Lukens, has since been increased by the observation of Price, Cori, and Colowick that insulin and anterior-pituitary extract are antagonistic to hexokinase. W. T. Salter, writing on euthyroidism and thyroid dysfunction, emphasises the clinical value of determinations of the level of protein-bound iodine in the blood.

L'hypertonie de décérébration chez l'homme

PIERRE MOLLARET, médecin des hôpitaux de Paris, professeur agrégé à la Faculté de Médecine, chef de service à l'Institut Pasteur; IVAN BERTRAND, directeur à l'École pratique des Hautes Études et de l'Institut de Neurobiologie (Salpêtrière). Paris: Masson. Pp. 15 Fr. 180.

THIS study of decerebrate rigidity (or, as the authors prefer to call it, "decerebrate hypertonia") is built round the detailed observation of a single case, in a man of 34 who fell a victim to Economo's encephalitis at the age of 17 and was nursed for the rest of his life in the Salpêtrière. During this long time he lay in a condition of mutism and paralysis in extension, voluntary movements being limited to the eyelids and upward movements of the eyes. The strict localisation of the lesions of this case to the substantia nigra, the commissure of Forel, and the red and dentate nuclei, combined with this clinical picture, leads the authors to argue in favour of Sherrington's original conception of decerebrate rigidity. The historical background and physiology of the neurological condition are traced, in the course of which the authors criticise the more recent attempts by British neurologists to amplify and, as they consider, confuse Sherrington's conception.

Mothers in Jobs

> "An employer should not dismiss a woman simply because she marries or because she is pregnant but only if, for medical or other reasons, she is no longer fitted to her job and if no alternative work can be offered her."

P.E.P., in a somewhat optimistic broadsheet,[1] support the right of the mother to go to work if she wants to. Probably most British women regard a job as something to fill the interval between school and marriage, and accept as their serious work the task of rearing their children and looking after their homes; and if the State looked on this work as comparable in value with any other kind of work, the time and energy which mothers devote to it would not be limited by the earning capacity of the husband. Nevertheless if some accessory services—such as day nurseries and help in the home—were provided on an adequate scale, mothers might be released to share in industrial work, anyhow for part of their time. The war brought some changes on these lines. Family allowances recognise the value of children and so, indirectly, of mothers; day nurseries gave mothers more freedom for work when their services were acutely needed; and the usual discovery was made that women have deft fingers. In fact "there was found to be a greater reserve of ability among the unskilled and semi-skilled than had been imagined. This applied with particular force to women workers—married or single—who had in the past been confined mainly to the unskilled occupations." All the same, in an effort to fulfil its two purposes of raising a new generation and of providing labour and goods for this one, the State makes conflicting demands on women. If there is to be a labour shortage, as many women as possible must be helped to share in industry; yet a long-sighted policy would favour the bearing and rearing of children, for this will automatically lessen man-power shortage in the future. In this situation P.E.P. advise that women who want to work outside their homes must be allowed to do so by the removal of restrictions, occupational bars, and other impediments. If the principle of equal pay for equal work is accepted, women will cease to be "cheaper" than men and so may find their opportunities reduced in some occupations; in others they will no doubt hold their own, or perhaps gain ground. P.E.P. are concerned to reduce the conflict between motherhood and employment, and to remove the economic necessity which forces poorer mothers to remain at ill-paid work when they should, and would rather, be with their children.

Experience in industry shows that most pregnant women give up work between the 26th and 28th weeks, and comparatively few stay till the later stages of pregnancy. Of 83 women followed up, only 18 had returned to any sort of work 17 months after confinement. In 1931 three-quarters of all married women at work were in domestic service, the textile industry, and the clothing, distributive, and catering trades—all of which use much cheap casual labour. And though the war gave all women the chance of earning good pay, a return to normal peace-time conditions will again drive expectant mothers mainly into poorly paid and insecure jobs, chiefly because the service they have to offer is uncertain. Yet it has been shown quite clearly that properly safeguarded factory work is not harmful to pregnant women, and indeed may be specially suited to them because they can be supervised and transferred to appropriate types of work as need arises. Moreover, "factory or office work may be less exacting than looking after a house, attending to children, and standing in queues"—though many women combined both duties during the war. The main danger to the working mother is this double burden of job and housework, which may leave her no time to seek proper antenatal care. Some firms, during the war, arranged for antenatal care to be given in the factory, and found that women reported their pregnancies earlier to the factory nurse than they would have done to an outside clinic. P.E.P. feel that when the National Health Service is in action it would be better to encourage women to make full use of the outside maternity service rather than to duplicate such services inside factories. This can only be achieved if the mother has no fear of dismissal when she reports pregnancy, and if she is given time off to attend the clinic. At present medical supervision of mothers in direct relation to their work is unusual; yet it is essential, and can only be done properly by a doctor who understands the kind of work she is doing. The suggestion that the local antenatal clinic should hold sessions in or near the factory seems specially promising, and official food supplements might well be issued at the factory.

Apart from care and supervision, the working mother needs financial security and sufficient help with her child and her housework. She is at present entitled to the same maternity services as any other mother (some free, some paid for at fixed rates), and—under National Health Insurance—to free supervision by her panel doctor during pregnancy and after lying in. She has no statutory period of leave, and no maintenance allowance while she has to stay away from work. Under the Factory and Public Health Acts she may not be employed in industry during the first four weeks after delivery, but this rule is difficult to enforce and often ignored. She gets a single cash benefit of £2 (£4 if her husband is also insured) under the N.H.I. scheme; and sickness benefit, though not officially granted for pregnancy, is usually paid during the lost six weeks if a claim is made. Under the N.H.I. Acts, sickness benefit may not be paid "in any circumstances whatever" during the four weeks after confinement. Some 20% of married and 30% of unmarried mothers draw sickness benefit at some time in the three months after childbirth. Benefit rates are only a fraction of the amount needed for full maintenance of mother and child, so the temptation is strong for the needy mother to work up to the time of her confinement and to return to work as soon as she gets up. The Washington Convention of the International Labour Office in 1919 laid down as a minimum 12 weeks' maternity leave and cash benefits sufficient for "full and healthy maintenance for mother and child"; but this ruling was never ratified in Britain. In any case the period is much too

Vitamins in diseases of the muscular system

Condition	Indications	Therapeutic Agents
ATONIC CONSTIPATION	Lack of tone affects the intestinal musculature A mixture of the B vitamins, preferably *in the form of food is found most* effective	**BEMAX** One heaped tablespoonful provides : 50/60 calories. *0 25/0 5 mg Vitamin B_1.* 1 0/1.5 mg available Iron and appreciable amounts of the Vitamin B_1 complex and Vit. E.
SPASTICITY ; paralysis agitans.	Vitamin B_6 has been found to reduce the muscular rigidity in ambulatory patients in whom the condition has not been of long standing.	**PYRIDOXIN Vitamins Ltd. :** 10 mg tablets, one or more thrice daily or 50/100 mg. daily by injection.
THE MYOPATHIES, muscular dystrophies and amyotrophic lateral sclerosis.	The disturbed muscle metabolism with increased creatinuria is found to respond in some cases to Vitamin E together with other factors in whole wheat germ	**BEMAX**. At least 1 oz. daily together with **FERTILOL** (whole wheat germ oil stabilised and standardised) *one 3 mg capsule thrice daily*
FIBROSITIS	The condition responds to wheat germ oil applied locally as an inunction and taken by mouth	**FERTILOL** one 3 mg capsule daily for prolonged periods possibly with Fertilol Cream applied locally
HYPOTONIA pink disease.	The association of hypotonia with loss of weight and digestive disturbances calls for high doses of both B_1 and B_6	**VITAMIN B_1 (Aneurin hydrochloride) Vitamins Ltd :** 10 mg daily by mouth or injection. **PYRIDOXIN Vitamins Ltd.:** 10 mg. daily by mouth or 50 mg. by *injection. Later* **BEMAX** *can be given as part of the diet.*

Further particulars of the various vitamin products are obtainable on request from :

'THIAZAMIDE' Sulphathiazole

TRADE MARK BRAND

Sulphathiazole is one of the most active of the sulphonamide drugs for the treatment of pneumococcal, gonococcal and haemolytic streptococcal infections.
Many regard it as the sulphonamide of choice for the treatment of urinary tract infections and gas gangrene.

TABLETS

Containers of 25 x 0.50 Gm.
" 100 x 0.50 Gm.
" 500 x 0.50 Gm

Containers of 25 x 0.125 Gm.
" 500 x 0.125 Gm.

PASTE

Contains 5 per cent. of sulphathiazole and is intended for topical application in cases of impetigo and in certain other coccal skin conditions.

Containers of 1 ounce.
" 16 ounces.

STERILISED POWDER

For topical application by sprinkling on superficial or open wounds for prophylaxis and early treatment.

Containers of 15 Gm.

CREAM

Contains 5 per cent. sulphathiazole and is used when the necessity arises for a soft water-miscible cream—e.g. as a first-aid dressing in burns, superficial cuts, etc.

Containers of 1 ounce
" 16 ounces

STERILISED POWDER

With 1 per cent. w/w Proflavine Hemisulphate For the prevention and treatment of wound infections by dusting over the surface.

Containers of 15 Gm.

EYE OINTMENT

An application which will secure prolonged contact of the therapeutic agent with the superficial tissues of the eye in chronic eye infections. It contains 10 per cent. of sulphathiazole.

Collapsible tubes of 5 Gm.

TREATMENT SHOULD BE DISCONTINUED AFTER FIVE DAYS

"May & Baker's sulphathiazole preparations are protected by British Patent No 533 495 which was granted on 24th May, 1946 jointly to May & Baker Limited and Ciba Limited of Basle"

manufactured by **MAY & BAKER LTD.**

hoping that rest and general measures will mitigate the cardiac damage It seems possible, however, that succinate will replace salicylate. GUBNER and SZUCS[6] treated 65 cases with an average of 4·5 g. of sodium salicylate daily, and compared these with 55 cases receiving a similar amount of the calcium double salt of benzoic acid and succinic acid benzyl ester together with ascorbic acid. The succinate group showed a shorter clinical course, a much lower incidence of carditis (as shown, for example, by prolongation of the P-R interval), and an apparently lower incidence of valvular disease developing within one to six months. Succinic acid acts as a catalyst in some biological oxidations, and there is enough evidence of derangement of tissue oxidations in rheumatic fever to make its trial plausible on metabolic grounds. The clinician will await further experience.

Surgery of the Œsophagus

THE widening scope of surgery in the treatment of diseases of the œsophagus is illustrated by the spate of technical modifications and the increasing size of published series, compared with the isolated protocols of a few years ago.

Malignant disease comes in for most attention, and CLAGETT[1] now reports 54 operations for carcinoma of the cardia of the stomach or lower œsophagus using the thoracic approach. Of these growths, 24 were inoperable but no complications resulted from the thoracotomy. In the other 30 the growth was resected and continuity restored, with only 5 deaths. It should be noted that only 3 of these were defined as œsophageal carcinomata, the remaining 27 being growths of the upper stomach. CLAGETT also records 2 resections for benign conditions. The virtue of this route in the approach to high gastric lesions has been clearly established. Lesions in the middle third of the œsophagus lend themselves less readily to operation. It has been shown that by mobilisation of the stomach well up into the chest, after incision of the diaphragm, an œsophago-gastrostomy as high as the arch of the aorta is practicable.[2] Most of these anastomoses have been performed on the left side, though IVOR LEWIS[3] has had good results with a right-sided thoracotomy and anastomosis after preliminary abdominal mobilisation of the stomach.

Some benign strictures and high growths cannot be dealt with in this way, and continuity between pharynx and stomach can then be established only by some form of extrathoracic gut or skin tube method. With stricture, excision of the œsophagus is unnecessary, and an artificial gullet is the method of choice; the same applies to total removal of the œsophagus after the Torek and pull-through types of operation. The skin funnel operation has the disadvantages that the funnel is inert, and may become lined with and clogged by hair. Jejunal or gut loops, if properly constructed, convey food from the pharynx to the stomach without artificial assistance, but their length is limited by the distance to which the mesenteric blood-vessels will reach. YUDIN[4] in a series of 80 cases used a skin tube in 6 instances and a jejunal loop in 16; in the remaining 58 patients the two methods were combined. A recent modification mainly applicable to strictures consists in using an isolated jejunal loop as a free subcutaneous graft. LONGMIRE and RAVITCH[5] have shown that a long segment of gut can be exteriorised and placed subcutaneously, with its blood-supply initially left intact. The gut is then in stages surrounded by skin flaps to make a tube, and the mesenteric vessels are gradually and increasingly constricted until the gut-skin tube is viable. After division of its original blood-supply the tube is moved, again in stages, to the front of the sternum, where it is ultimately united to the cervical œsophagus and stomach. This procedure is tedious, involving many operations, but only the initial abdominal operation need be regarded as a major undertaking. The method ensures that an adequate length of jejunum is available for the artificial œsophagus; and it overcomes the principal objection to the usual operation, in which the length of bowel is determined by the mobility of the mesentery. Localised strictures in the lower œsophagus are more easily dealt with; failing gradual dilatation, they can usually be treated by a plastic operation on the lines of a pyloroplasty. With severe or long narrowings, an anastomosis between stomach and œsophagus through a small diaphragmatic incision will by-pass the stricture satisfactorily. CLARK and ADAMS[6] have practised one form of this operation in 5 cases; in 3 no known ætiological factor was established, while in another case the stricture appeared to be associated with generalised scleroderma.

For the many young people with œsophageal stricture or cardiospasm the chances of cure by radical surgery should be carefully considered before the patient is condemned to a life of dilatations or bougie swallowing. Furthermore, the difficulty in differentiating between carcinoma and some forms of stricture makes it imperative to consider thoracotomy in any case of doubt.

MEDICAL STUDENTS AND THE BILL.—The British Medical Students' Association sent a questionary on the National Health Service Bill to 10,106 students in medical schools in England, Wales, and Scotland. Of the 3801 (37·6%) who replied, 17% were definitely opposed to the principle of a comprehensive National Health Service, while over 80% were in favour. As to whether the present Bill will improve the medical services opinion was almost evenly divided. A small majority preferred the hospitals to remain under present administration, and a large majority disapproved of the transfer of voluntary hospital endowments to a new fund for redistribution.

Assuming that there is to be a service, opinion was strongly in favour of practitioners and specialists being allowed to conduct private practice along with their work in the service, as is proposed by the Bill. The combination of salary and capitation fees was approved (64%), though 18% favoured capitation fees alone and about 12% salary alone. The prohibition on the sale of N.H.S. practices (as proposed by the Bill) was accepted by 53% to 40%, but the power of the Medical Practices Committee to prohibit a doctor from practising in a particular area was not approved (47% for, 50% against). Nearly 60% disagreed with the composition of the local executive councils: where a reason was given it was that the councils should include more professional men.

Despite this disagreement about details, and uncertain approval of the Bill as a whole, over 60% of the students who answered the questionary expressed a willingness to work in the new National Health Service, provided remuneration is suitable and the regulations made by the Minister are acceptable.

short for the best interests of the child. The Royal College of Obstetricians and Gynæcologists have suggested that the mother should be free from all outside responsibilities for the first six months of the child's life—a view which is as strongly supported by psychological as by physiological findings. The introduction, under the National Insurance Act, of a weekly maternity benefit of 36s. for 13 weeks, to be paid on condition that the mother abstains from work, will do something, but clearly not enough. P.E.P. would like an extension of the period to be considered at once. Moreover, for the mother who has no husband to supplement it, the rate is too low, even when family allowances are taken into consideration. A National Assistance Service, to inquire into individual cases, is thought to be the solution; but the word "assistance" in the title of an official body has now an unpleasing sound in many ears. Public Assistance, carrying on the old poor-law stigma, is not always administered with tact and consideration. A special children's allowance to be paid to mothers with no source of income but their own earnings would meet the case better. The development of nursery schools of the best type and the growth of home-help services are also essential if mothers are to take part in industry without detriment to their main career; for the old sneer about the woman's place being the home gains a different significance once we realise that the output of the home compares favourably with that of the workshop—that children, in short, are more valuable than commodities.

Salicylates in Acute Rheumatism

THE generally accepted view of the action of salicylates in rheumatic fever is that they cause the fever and the arthritis to subside but do not affect the fundamental course of the disease or the development of endocarditis and valve lesions. It is still uncertain whether their febrifuge effect is merely that of an antipyretic acting on the temperature-regulating centre, or whether it is more complex and in some way specific to rheumatic fever. Doubt has also been expressed as to whether the joint effect is anything more than analgesic, seeing that in the natural course of the disease a given joint is swollen and painful usually for only a few days. Recent work in America has attacked these problems afresh, but as yet no finality has been reached.

In 1943 COBURN[1] attracted considerable attention for a claim that sufficiently high doses of salicylate suppress the rheumatic inflammatory process and may prevent lasting cardiac damage. With a new chemical method he was able to determine salicyl radicle concentrations in blood. To maintain a plasma salicylate level of 35 mg. per 100 c.cm. a daily dose of 10 grammes or more of sodium salicylate is necessary, and to reach that level quickly the early doses must be given intravenously. Of 38 patients with rheumatic fever so treated—young men from the American Navy—all are said to have escaped valvular heart disease, while of 63 similar cases treated with only enough salicylate to relieve the symptoms 21 developed valve lesions. Unfortunately the details, and especially the duration, of subsequent observation are not stated, and the conclusion must be accepted with reserve. Yet the case-records, showing relief of symptoms in a few hours with intravenous salicylate, the fall of temperature in 1–2 days, and the return of blood-sedimentation rates almost to normal in a week or two, are impressive. In some severe cases salicylate levels of 60 mg. per 100 c.cm. were reached and except in one patient who developed a toxic psychosis the only untoward effect mentioned was mild tinnitus. At John's Hopkins Hospital MURPHY[2] tested COBURN's claim by making a careful study of 12 patients with acute rheumatism receiving doses of salicylate large enough to maintain plasma salicylate levels of over 30 mg. per 100 c.cm. in nearly every case. The diameters of 24 swollen joints were accurately measured: 4 had decreased before salicylate therapy was begun; 2 decreased within twenty-four hours, 3 in forty-eight hours, 6 in up to five days, 2 after five to eight days, and 5 not at all in twenty-one days; 2 joints became involved for the first time on the fifteenth day of continuing salicylate therapy. Furthermore these patients developed various fresh rheumatic lesions during the intensive salicylate treatment, such as nodules on tendon sheaths, pneumonitis, tenosynovitis, and episcleral nodules; and some of these were confirmed by histological study. MURPHY concludes by doubting the accepted view that salicylates promote the subsidence of rheumatic joint inflammation. WÉGRIA and SMULL[3] compared 21 cases of rheumatic fever given salicylates in doses that promptly established and maintained 35–50 mg. salicylate per 100 c.cm. blood, and 19 cases treated with smaller doses. They could see no difference in the duration of the attack or in the behaviour of the sedimentation-rate of the two groups. Of toxic reactions, in the "adequately treated" group they describe tinnitus and deafness as common; vomiting as infrequent; hyperpnœa and tachycardia as occurring at levels of blood salicylate over 50 g. per 100 c.cm. MANCHESTER,[4] from an American naval hospital, accepts COBURN's view of the effectiveness of salicylates in suppressing inflammation and preventing cardiac residua, and describes in greater detail the toxic effects of continued high dosage. Hypoprothrombinæmia develops early, but is not severe and does not progress. Delirium can be caused by rapid intravenous infusion, raising the blood salicylate level too quickly. Hyperpnœa is due to acidosis and can be prevented by the simultaneous administration of alkali. JAGER and ALWAY[5] report on 26 cases of acute rheumatic infection treated with a long and intensive course of salicylates. Their results are not uniformly favourable, since both raised sedimentation-rates and other evidences of rheumatic activity persisted in many patients. Nor, as they say, is the follow-up adequate.

So far, then, the American evidence is conflicting. The advocates of intensive salicylate therapy write from naval hospitals, and it may be that rheumatic fever behaves somewhat differently in picked young men, so that results in them are not comparable with those in mixed general hospital patients. There seems no need as yet for doctors on this side of the water to depart from their time-honoured practice of giving salicylates by mouth in rheumatic fever, in doses just large enough to induce tinnitus, for at least as long as the fever and the arthritis last, and of

or November, he has given notice to the Insurance Committee in writing of his desire to transfer, whereupon he will be entitled to transfer as from the end of March, June, September, or December next following, but such transfer can be effected only if the new doctor agrees to accept him. If our correspondent tries to take advantage of this regulation, his present doctor will probably tell him that he must wait until his old doctor has been back for a year.

The protection of practices scheme is supposed to apply in exactly the same way to private patients, but these do not hold medical cards and when applying for treatment they often omit to explain that they are really patients of an absentee doctor.

MEGALOBLASTIC ANÆMIA IN CHILDREN

ANÆMIA with high colour-index and large red-blood cells does occur in infancy and childhood, but the frequencies of its causes are quite different from those in adult life. The commonest cause in childhood is nutritional deficiency, either primary or secondary to cœliac disease; Blackfan and Diamond [1] have seen it in acute infections in infants with temporary achlorhydria; hæmolytic syndromes, like erythroblastosis fœtalis and familial acholuric jaundice, and leukæmias are not uncommon causes. There has been much argument about the incidence of true pernicious anæmia before adult life and the evidence has been reviewed by Peterson and Dunn.[2] They point out that the following criteria are essential for establishing the diagnosis of pernicious anæmia *in childhood*: macrocytic anæmia, gastric achlorhydria resistant to histamine stimulation, megaloblastic change in the bone-marrow, a specific response to liver treatment, and the necessity for continued treatment to prevent a relapse. Examined by this strict standard, every case but two reported up to 1942 failed to qualify; not a few had free HCl in the gastric juice, others showed no relapse after liver treatment was stopped, some were clearly nutritional cases, and in many the evidence was inadequate or rested primarily on post-mortem changes.

Pohl [3] described the case of a girl of 13 years who was studied for 4 years and presented all the features of pernicious anæmia: Dedichen [4] reported a macrocytic anæmia in a child of 13 months in whom repeated relapses were observed over a period of 3 years whenever liver treatment was stopped. Peterson and Dunn describe a case of their own, in a child of 13 months who was admitted because of diarrhœa and pallor; the red-cell count was 810,000 per c.mm., hæmoglobin 2 g. per 100 c.cm., colour-index 0·82, white cells 62,000 per c.mm., with 90% lymphocytes and 8% "smudges," and reticulocytes 14%. It is not surprising that pernicious anæmia did not figure in their original differential diagnosis; the child was transfused and not given liver until 3 months later, when it produced a surprisingly good effect. The patient relapsed several times; during her fourth relapse, 3½ years later, the bone-marrow proved to be megaloblastic; gastric achlorhydria had been noted previously. It was found that the girl had an iron-deficiency, and when this was remedied she improved remarkably and the blood-count became normal. Nine months later a mild normochromic anæmia was remedied by increasing the dose of liver extract; the white cells were then normal and with normal distribution. That such an extraordinary case should be reported as pernicious anæmia emphasises the diagnostic difficulties that arise in children; yet, apart from the absence of macrocytosis and the curious lymphocytosis, the case conformed to all the criteria given above, and the lack of macrocytosis is attributed to the iron-deficiency.

Davis [5] has described 3 cases of macrocytic anæmia in children. The first was in an underdeveloped girl of 13 years who had a megaloblastic marrow and, at first, free acid in the gastric juice; she was treated, but 3 years later was seen in a relapse when she had achlorhydria and responded to a purified liver extract used for treating pernicious anæmia; it is clear that had she been seen for the first time at the age of 16 she would have been regarded as a case of pernicious anæmia. His second patient was a boy of 14 years who had achlorhydria and megaloblastic marrow; a purified liver extract was ineffective, but proteolysed liver by mouth and a crude liver extract parenterally produced a remission after which no further treatment was needed. The third patient, a girl of 3 years, resembled the second, but gastric acid secretion was present. Neither of these patients would be classified as pernicious anæmia. Recently Zuelzer and Ogden [6] in Detroit have drawn attention to a macrocytic anæmia in infants aged up to 18 months that they found to be quite common, and they give details of 25 cases. The bone-marrow, aspirated from the femur, was typically megaloblastic, gastric achlorhydria was present in some; the anæmia was severe and clinically the patients had pallor, fever, vomiting, diarrhœa, and sometimes petechiæ. All except 5 of the infants responded rapidly to liver extract or to folic acid, and so far these have not relapsed; the 5 exceptions died from complications, mostly infective.

From all this evidence it can be deduced that a macrocytic anæmia with megaloblastic change in the bone-marrow is fairly common in infancy and childhood. It should be distinguished from other forms of macrocytic anæmia, since most of the patients respond to liver extracts; ordinary crude extracts should be used and not the purified extracts specially designed for the treatment of pernicious anæmia, like '*Anahæmin*'; Zuelzer and Ogden's results suggest that it will be worth while to try folic acid for these patients. It is doubtful whether true relapsing pernicious anæmia of adult type does occur before puberty, and the outlook for the children who seem to have the disease is relatively good, since they nearly all show a lasting response to liver, and if they weather the original crisis they will recover permanently. It seems reasonable that the name "megaloblastic anæmia," which describes the main diagnostic features of the disease without confusing it with pernicious anæmia, should be adopted.

MECHANISM OF PAIN

IN his founder's lecture at the annual congress of the Chartered Society of Physiotherapists on Sept. 14, Prof. G. W. Pickering spoke of the pain mechanism in man as consisting of three essential parts: the sensory nerve-ending or receptor, the nerve-fibre or conductor, and the brain or cortical analyser. Receptors were very numerous in the skin and liberally provided in the deep fascial and muscular structures, but rather few in the subcutaneous tissues. The parietal layers of the serous membranes were well supplied, but the visceral layers and the viscera themselves not at all, though perhaps there was some evidence that the pains of angina and peptic ulcer do arise directly in the organs concerned. Periosteum and ligaments were sensitive, spongy bone slightly so, compact bone and joint surfaces insensitive; arteries possessed more receptors than veins, and the meninges were profusely studded with them, whereas the brain itself had none.

The tissue changes which produced excitation of these receptors might be physical, a deformation of surface producing alteration in configuration and tension; or chemical, like the pain of claudication due to the accumulation of metabolites in muscle-fibres, peptic-

THE BASLE MEETING

LAST week's British-Swiss medical conference (see p. 464) was more than once likened to a peace conference; and, as at peace conferences, much of the most important work was done outside the formal meetings. Workers in both countries were eager to hear, at first hand, what had been done in the long period of segregation, and were often astonished at the parallel developments in the war years. The papers themselves, to which the *Schweizerische medizinische Wochenschrift* devoted a special number in English, gave an excellent symposium of recent advances in both countries. It may be hoped that the visitors learnt something of the example by the Swiss Academy of Medical Sciences in its preparations for the meeting. The papers themselves were all read in English with simultaneous translation, through earphones, into German—a device whose excellence has been equalled, Sir Heneage Ogilvie remarked, only at the Nuremberg trials. Delegates might perhaps have found it easier to make contact with one another if each had worn a rosette bearing his name; and it might have been an advantage to discuss each paper after it was read rather than at a single discussion in the evening. But these are small points.

Swiss doctors are eager to hear more of British medicine; it was therefore disappointing to find that, despite demand, the leading bookshops, though stocking American works, had been unable to obtain British textbooks, and, in particular, textbooks of medicine. The value of sending British publications to other countries is not solely commercial; and it is to be hoped that the precedent of the *British Medical Bulletin*, which is readily obtainable overseas, will be applied to books before the habit of buying those published elsewhere has become too firmly established.

At the banquet given by the academy, Prof. Karl Wegelin, the president, emphasised the strength of the bonds between Switzerland and Britain. Dr. Peter, president of the Basle council, spoke with eloquence of the feeling in that city, so near the frontiers that the sounds of war in both France and Germany had been heard. The Swiss people had, he said, been sustained by the spirit of the British, who had preserved democracy for Europe and the world; the best hope for the future lay in closer personal relations, and it was such meetings as the present that helped to foster international understanding. Professor Lutz, dean of the medical faculty at Basle University, called for an objective approach to international affairs; and Dr. Leuch welcomed the guests on behalf of the Swiss federation of doctors. Sir Heneage Ogilvie, replying for the visitors, showed a knowledge of Switzerland which gratified his countrymen no less than their Swiss hosts.

EXTRANEOUS CAUSES OF UTERINE BLEEDING

WHEN faced with a case of menorrhagia or epimenorrhœa, the average clinician thinks of organic pelvic disease, whose existence he proves or excludes by pelvic examination. If he finds the genital tract clinically normal, the condition is labelled as functional or endocrinopathic bleeding, and there the matter may rest. It is important to realise that there are other causes of bleeding and that organic disease, if present, may not necessarily be the primary cause of the hæmorrhage.[1]

Benign myometrial or adnexal lesions can hardly be considered as primary factors in uterine hæmorrhage, though they may aggravate bleeding by interfering with hormonal control or the dynamics of the pelvis. It is, moreover, questionable whether it is fair to blame an endocrinopathy for all or many of the uterine hæmorrhages which are attributed to that cause. The influence of the central nervous system is well known: fright, fatigue, sexual excess, change of environment, or emotional shock often lead to irregularities in menstrual function. The menstrual rhythm may also be disturbed by physical agents, such as change of climate or of weather, and the effects of high altitude; thus waitresses working on the Jungfrau-joch had to return to lower levels because of severe menorrhagia. Not only the pituitary and the ovary but other endocrine glands affect menstruation. Hypothyroidism in 75% of cases leads to menorrhagia, whereas hyperthyroidism as a rule results in hypomenorrhœa or even amenorrhœa. Diabetic women tend to suffer from ovarian degeneration, but if stabilised with insulin menstrual function remains normal. Infectious diseases and upper respiratory infections such as the common cold, influenza, and pneumonia may delay the onset of a period.

Blood dyscrasias must also be considered: more than 50% of women with idiopathic hypochromic anæmia have menorrhagia. Essential thrombocytopenic purpura may be suggested by severe uterine bleeding at the menarche. Secondary thrombocytopenia from such causes as malignant disease, leukæmia, septicæmia, arsenical poisoning, and X rays and radium must not be forgotten; pseudo-hæmophilia is a further cause of menorrhagia, and idiopathic hypoprothrombinæmia and hereditary telangiectases are among the rare causes. Deficiency of vitamins B, C, and K has often been suggested as a possible cause of excessive uterine bleeding; and various types of heart disease and chronic nephritis must not be overlooked.

The gynæcologist confronted with a case of menorrhagia should recall that he is not dealing with an isolated region between the umbilicus and the perineum, and that curettage and endocrine treatment are not the final answer for every patient with functional bleeding.

SNAGS IN PROTECTION OF PRACTICES

A CORRESPONDENT complains that, being an insured person, when his family doctor returns after 7 years in the Forces he must give up his present doctor for at least a year, whether he goes back to his old doctor or not. This is quite true. Men who have served in the Forces expect reinstatement in their jobs when they are released, and the scheme for the protection of practices is an attempt on the part of doctors to secure that those of their colleagues who have been on national service can return to their jobs on release. Schemes vary in detail, but broadly speaking they provide that doctors who have joined—and this covers the great majority of insurance practitioners—will refuse to accept on their own behalf any patients of an absentee doctor until a year after the absentee's return or a year after the termination of the emergency, whichever is earlier. They have agreed that, if a patient of an absentee doctor applies for treatment they will tell the patient that they will attend only on the absentee's behalf. They are also required to display in their surgery a printed notice intimating that during the absence of a doctor on Service his patients will be attended by a home doctor in the neighbourhood and on the return of the absentee they will be expected to seek any advice required from him.

If our correspondent has removed from the district in which his old doctor practised he can transfer permanently to the list of another doctor by using part "B" of his medical card; otherwise, if he wants to transfer to another doctor he should ask his old doctor to sign part "C" of his medical card consenting to an immediate transfer. If the doctor signs—but he is not compelled to do so—this will absolve other acting practitioners from their pledge so far as that particular insured person is concerned. The Medical Benefit Regulations provide that an insured person may transfer at the end of a quarter if, not later than the last day of February, May, August,

WORLD PROBLEMS OF NUTRITION

F.A.O. CONFERENCE AT COPENHAGEN

FROM OUR CORRESPONDENT

THE Food and Agriculture Organisation held its second annual conference at Copenhagen from Sept. 2 to 13. Its principal work was to consider the proposal of the director-general, Sir John Boyd Orr, F.R.S., for the establishment of a World Food Board. This board would attempt to stabilise prices of agricultural commodities in the world market, providing the necessary funds; to establish a world food reserve equipped for any emergency that might arise through failure of crops in any part of the world; and to coöperate with organisations concerned with international credits for industrial and agricultural development and with trade and commodity policy. The conference appointed a commission to sit at once and draw up a detailed plan for the board. This is to be submitted to an adjourned meeting of the conference early next year.

The standing advisory committee on nutrition, whose chairman is Lord Horder, in its first report to the director-general recommended governments to keep a careful watch on the food situation in their countries, for which purpose, it says, diet surveys are of great value in assessing dietary defects and formulating food-supply requirements. F.A.O. should ask nutrition experts in the various countries to study the methodology of diet surveys with the ultimate aim of securing comparability of results and perhaps evolving standard types of survey. On school feeding the committee recommended that F.A.O. should study school-feeding programmes in different countries, covering all ages, with reference to the type of food-supplies, organisation, cost, and effects on health. Information about successful methods of school feeding may assist governments to develop satisfactory programmes, particularly where school feeding has not been organised.

The committee laid stress on the need for studying milling, processing, fortification, and preparation of cereals in relation to nutrition. It suggested that F.A.O. should study a number of staple cereals, such as wheat, rice, maize, and rye, to ascertain the effect of these operations on their nutritive value. The relation between extraction-rates and vitamin-B_1 content of wheat calls for investigation. The "fortification" of wheat-flour or bread includes the addition of vitamins, calcium salts, skim-milk, and other kinds of flour, such as soya-bean flour. Information about the methods adopted by different countries for conserving or enhancing the nutritive value of wheat-flour would be of value to other countries. Parallel problems of rice-processing should also be examined. Highly milled raw rice is poor in vitamins, notably B_1, and investigation is needed to decide which methods—e.g., under-milling, parboiling, and enrichment—are likely to be most satisfactory in the rice-eating countries. The effect of household methods on the nutritive value of rice should likewise be studied; for instance, the washing of raw rice may remove a considerable proportion of certain nutrients. There seems to be a relation between the processing of maize and the incidence of pellagra; the F.A.O. nutrition programme should therefore include a survey of the methods of milling, processing, and preparing maize.

Perishable foods, such as milk, vegetables, and fruits, also call for special attention if their nutritive value is to be safeguarded; and further study is required on the utilisation of whole-fish meal and the inclusion in canned meat of ground fresh bone.

EDUCATION IN NUTRITION

This subject has three main aspects: (1) the training of specialised workers; (2) the instruction of persons able to help in the campaign for improving nutrition; and (3) the education of the people with the object of improving their dietary habits. In studying and attacking nutrition problems the lead must be taken by a "core" of specialised nutrition experts. To accelerate progress systematic instruction in food and nutrition, both theoretical and practical, must also be given to administrators, agricultural experts, food technologists, teachers, nurses, and social workers. The committee agreed unanimously that the teaching of nutrition in various curricula, especially medicine, is unsatisfactory. University authorities and others concerned with higher education should give nutrition a place in their curricula in keeping with its importance. The position of the doctor, the committee point out, is unique: his opportunities of teaching and applying the principles of nutrition are unequalled by those of any other member of the community. His training in nutrition should therefore be thorough, and progress is not likely to be made here until nutrition holds a conspicuous place in the medical curriculum approved by the statutory bodies which control it in the various countries. The principles of nutrition should be inculcated in the child at home and at school, and for the teaching of sound dietary habits to children school feeding is useful. Similarly, the organised feeding of workers is a valuable means of teaching adults.

The education of housewives is of great importance, and one means of providing it is through courses in domestic science, which should be introduced in countries where they do not exist. Voluntary groups, properly guided, can do a good deal to spread a knowledge of nutrition among the general public. Advertisements educate the public, and therefore advertisement of the nutritive value of food products should be controlled. In countries deficient in food the emphasis in education should be laid on the best means of utilising available supplies; in those with a surplus the need for consuming diets of the highest standards should be stressed.

The war experience of countries with comprehensive control plans—amounting almost to large-scale human feeding experiments—contains valuable lessons.

NATIONAL COMMITTEES

At the outbreak of the war national nutrition committees or councils existed in over thirty countries, many as a result of stimulus by the League of Nations. Only a few of these are still effective. The committee recommended, therefore, that a comprehensive report should be prepared on their present situation. Such committees may be identical with the F.A.O. national committees, but in many countries this is neither possible nor desirable, though the two committees should be closely associated. The nutrition committees must be guided by trained nutrition workers, have adequate facilities and financial support for research, and be able to influence their governments. They must have the coöperation of governmental and other agencies—e.g., ministries, labour unions, domestic science organisations, and charitable societies—that are anxious to improve the nutrition of the population and possess the necessary means and personnel. Besides merely urging governments to establish committees F.A.O. should study realistically the conditions necessary for their satisfactory operation.

F.A.O. must know where to seek effective collaboration from nutrition organisations and workers, and an index of these throughout the world should be prepared. The staff of the nutrition division should establish contact with workers in various countries.

Nearly all practical nutrition problems will also concern the World Health Organisation. The committee recommends that a joint nutrition committee should be set up between the two bodies, which should consult together about the choice of their nutrition staff.

NUTRITIONAL STANDARDS

The nutrition committee of the conference, which has some common membership with the standing advisory committee, accepted its recommendations and suggested certain directions in which they could be implemented. It pointed out, for instance, that the expression of food commodities in terms of nutrients requires the use of appropriate tables on food composition. This does not mean a single international figure for each food, for there are real differences in the nutritive value of foods in different parts of the world. Nevertheless, the values used by countries in preparing statistical material for international consideration should be derived by com-ulcer pain from stimulation by acid, and the continued pain of burns. It was the analyser's function to receive these impulses after transmission, to relate them to past experiences, and to form an image for purposes of description. Sir Thomas Lewis had shown that the quality of pain arising in the skin surface was always the same whether the stimulus was pinching, pulling, or burning. With the skin anæsthetised and the deeper structures stimulated, the subject could always tell that the pain was not arising in the skin though he could not localise it to fascia or bone. Thus, from the point of view of quality, there were only two kinds of pain—one from the skin, and one from beneath the skin. Visceral pain was not distinguished in quality from ligamentous or muscular pain, and any other "qualities" were due only to mental associations and could be excluded by eliminating visual and other factors. The intensity of a pain was largely determined by the behaviour of the analyser. Hence the racial range of susceptibility, the emotional influence which produced the painless mutilations of religious ecstasy and the exaltation of pain by apprehension, and the effects of suggestion on the state of inhibition or excitation of the cortical analyser. It was interesting to speculate how much the beneficial results of physiotherapy were due to such suggestion. One of the most fascinating problems of pain was the phenomenon of reference. Skin pain was accurately localised, while visceral pain was not. It was to explain the fact that visceral pain did not correspond closely to the organ of origin that James Mackenzie introduced his conception of the viscero-sensory reflex with enhanced excitability of the particular cord-segment involved. More recently, Kellgren's[1] work on the segmental reference of pain excited from the interspinous ligaments had thrown further light on the whole subject.

In a sense, said Professor Pickering, it might be more reasonable to ask why pain was so well localised in the skin at all, rather than why visceral pain was referred. The answer probably lay in the increasing knowledge and experience gained by the cortical analyser in development, an education associated with visual knowledge of events in local areas of the body surface. This educability of the analyser was well shown in the fineness of touch acquired by the blind. With the deeper structures such an education was obviously impossible; there was much less correlation with outside influences, and the pain was felt over a wide area determined by the segmental nerve-supply.

PLAGUE VACCINE

DURING the last half century over forty million doses of plague vaccine have been issued by the Haffkine Institute in Bombay. These have been used in different parts of India whenever plague has appeared in epidemic form and it is claimed that thereby several million lives have been saved. The method of preparation of this vaccine has varied from time to time, especially in the last fifteen years, but during most of this period a broth vaccine killed at 65° C, as first introduced by Haffkine, was used; later, lower temperatures were used for killing the organisms.

The claim for the prophylactic value of this vaccine was based first on animal experiment, and then on the extensive field experience in the plague-stricken areas in India and elsewhere in the East. Statistics collected in India indicated that the vaccine reduced the chances of exposed persons becoming infected to a quarter and the chance of dying of plague to an eighth of what they would otherwise have been, whereas in Java it was claimed that the infection-rate was reduced to a third or a half. In 1907 Strong, working in the Philippines, used living avirulent vaccine with success, but he did not pursue this line of work because of the practical disadvantages of such a vaccine, and nearly forty years later his opinion on its impracticability on a large scale is unchanged. The value of the Haffkine vaccine began to be questioned in the early 1930s. Figures from Madagascar, Central Africa, and elsewhere seemed to indicate that the vaccine was useless, and the methods of obtaining the data on which the favourable claims had been based in India were severely criticised by statisticians. This led to a reinvestigation of the living avirulent vaccine, more particularly by Girard and Robic in Madagascar in 1933 and in the following year by Otten in Java. Animal experiments reveal a much higher protective value for the living vaccine than is ever obtained by killed vaccine; ten million doses were given in the Dutch East Indies up to 1941 without producing a single case of plague, and a tenfold reduction in the death-rate from plague was reported in those vaccinated.

It is now generally agreed that the living avirulent vaccine is more efficacious than any killed vaccine, and only the difficulties of its preparation and distribution have prevented its general adoption. The dangers inherent in the preparation of a living vaccine, especially in tropical countries, are obvious. There is apparently no danger that these avirulent organisms will regain their virulence, but if the vaccine is kept too long it loses its protecting property. The safe limits are between the 5th and 15th day after preparation; this is far too short a period to allow distribution in a large country such as India or among the far-flung fighting forces of the United States in the late war, to take two examples. The U.S. Services therefore used a killed vaccine, and they chose one containing 2000 million organisms per ml., of which 0·5 ml. was given as the first dose followed by 1·0 ml. a week to ten days later; "booster" doses of 1·0 ml. were given periodically when the danger from infection was imminent.

THE BASIC NURSING COURSE

WE have often put the case for a two-year course in practical nursing for all entrants to the nursing profession, to be followed—for those who wish to apply for senior posts or to specialise—by a much stiffer training, demanding a higher standard of theory than the present curriculum. We believe this would have the double advantage of reviving interest in nursing technique and research, and of developing to the full the abilities of every type of student, whether her bent is practical or academic or both.

It is encouraging to learn that the County Councils Association have now endorsed this policy. The *Public Assistance Journal*[1] announces that the association's executive council has accepted the following resolutions previously passed by the Association of County Medical Officers of Health:

1. There should be a basic training of two years for all nurses, some of which period should be spent in nursing the chronic sick. The training should be essentially practical.
2. After that training and on passing their appropriate examinations, the designation should be "Qualified Nurse."
3. A substantial number of nurses should receive further training in order to qualify them for positions of ward sister and higher. The appropriate designations to be settled later.

The proposal that every nurse should spend some time with chronic patients is particularly valuable, for it is precisely where the doctor and surgeon can do least that the nurse can do most. She should be encouraged to recognise and use her important opportunities for improving our care of such patients.

DR. T. WATTS EDEN, consulting obstetric physician to Charing Cross Hospital, and consulting surgeon to Queen Charlotte's Hospital and the Chelsea Hospital for Women, died on Sept. 22 at the age of 83.

---

[1] Kellgren, J. H. *Clin. Sci.* 1939, 4, 35.

[1] Sept. 6, p. 693.

parable methods and represent the nutritive value of food at the same stage in the flow from the farm to the mouth of the consumer. Most of the data now available on the nutritive value of foods refer to products as brought into the household (retail level) and provide information on the proportion of inedible material and the moisture content and nutritive value of the edible portion at this stage. The nutrient content of the edible portion may be considerably higher than that of the same portion of food "as eaten," because of waste and nutritive losses—both visible and invisible—during household storage, preparation, and serving of foods. Data on the composition of food as eaten will be increasingly necessary as correlations are sought between the results of dietary surveys and appraisals of the nutritional status of individuals and population groups. Accordingly the nutrition committee recommended that F.A.O. should arrange for joint consultation of experts in nutrition and food statistics from various countries who should develop the principles on which average food-composition figures used by individual countries should be based, and explore the means whereby comparability of data for international use can be attained, including, if necessary, the revision of tables now used for this purpose.

UTILISATION OF CEREALS

In addition to the study of the preparation of cereals recommended by the standing advisory committee, the nutrition committee draws attention to a broader aspect of the question: the utilisation of cereals, cereal products, and other plant products as human food or animal feeding-stuffs in such a manner that the nutritional needs of the population shall be best met. The best method of utilisation will differ in various countries, depending on the nutritive value of the cereals and products in question, the efficiency of their conversion by animals into human food, the relative cost of plant and animal products and their acceptability to the consumer, and the nutritive value of the diet of the population, particularly of the low-income groups. The committee accordingly recommended that F.A.O. should study the best utilisation of plant products for human consumption, either directly or through the animal; and the most economical and satisfactory balance between the production of meat and milk and between poultry-meat and eggs. Such studies would assist governments to plan their food policies so that food-production would be adapted to the physiological requirements of the people.

Rapid progress has been made in recent years in the chemical and microbial synthesis of foods and nutrients, such as yeast, fats, and vitamins. It is highly important that synthetic processes which may contribute to the improvement of nutrition and the alleviation of food shortage and dietary deficiency should be investigated and, if found advisable, their development stimulated. The committee heard a report from a representative of the forestry committee on the possibility of obtaining food by the saccharification of wood, and considered that the question of using saccharified wood for the production of food yeast should be further explored.

The committee pointed out that the national nutrition organisations recommended by the standing committee must be adapted to the governmental machinery of each country. Countries which contain a number of component units, such as federated states or self-governing communities, are urged to establish a central representative nutritional organisation. It recorded its opinion that the scientific evidence at present available does not indicate that, given similar environmental conditions, the physiological requirements of food for optimal growth, health, and physical efficiency are different for the peoples in the various parts of the world. It stressed the urgency of investigating food-supply targets.

The conference accepted both reports and passed them to the secretariat for action. The immense amount of correspondence, digestion, recording, and circulation which they involve is only a fraction of the whole work of the permanent staff of F.A.O.

THE OUTLOOK

An observer cannot help asking to what extent, when these voluminous surveys and advisory documents come into the hands of governments and other bodies in various parts of the world, their precepts will be put into practice, and how much of them will be neglected or suppressed. Though some of the less controversial advice may be followed, what weight will they carry when they conflict with political tendencies and commercial or national interests? Though the secretariat has done wonders in a short time, this vast programme of work must necessarily take years to execute. Even the World Food Board, the urgent need for which is admitted by all, cannot possibly under the most favourable conditions come into activity before next summer, and if the blue-print of the preparatory commission excites substantial controversy, its establishment must be correspondingly delayed. World events already move with dreadful speed, and that speed is accelerating. The obvious danger is that they will outstrip the organisation's good intentions and heroic work.

BRITISH-SWISS MEDICAL CONFERENCE

(*Concluded from p. 431*)

PHYSIOLOGY OF THE KIDNEY IN INFANCY

Prof. R. A. McCance (Cambridge) said that before birth the internal environment can be satisfactorily regulated by the placenta; indeed babies, normally developed in other ways, may be born with functionless urinary tracts. Little is known about the function of the kidney before birth; but it has been proved that the kidney of the newborn infant does not immediately assume all the functions it will perform in later life. The non-protein nitrogen of the blood may be higher for a few days after birth than later, and the uric acid in particular is raised. The serum shows signs of acidosis and may contain very high concentrations of potassium. In infants under 3 months, as in other young mammals, water is excreted less freely than at a later age. After the age of 1–2 years the urea-clearances of children are of the same magnitude as those of adults. A baby's urine is never highly concentrated; in the first few days of life the specific gravity averages 1012–1015, and the osmotic pressure 450 milli-osmols per litre, and in the later weeks and months the urine is usually very dilute. Even when an infant aged 14 days is deprived of water and the urine volume falls, concentrated urine is not normally produced; nor is the infant's normal dilute urine concentrated by injections of posterior pituitary hormone. It has been demonstrated, however, that a hypertonic urine is excreted, even by premature infants, if the salt-intake is sufficiently increased; these hypertonic urines are not a sign of good renal function.

Infants respond to the intravenous injection of sodium chloride (1 g. per kg. body-weight in 10% solution) and the oral administration of urea (1·7 g. per kg. body-weight with a minimum of water) by showing a moderate diuresis, a rise in the urinary osmotic pressure, and (despite this) a poor elimination of the test dose; the responses are obviously complicated, but it is clear that the normal infant's kidney can be very ineffective in the early days of life. In babies the glomerular filtration-rate is less than half that in adults; in the human infant, as in some other mammals, the rate depends on hydration, and quite mild dehydration may cause gross abnormalities in the serum chemistry, so that renal damage may then be erroneously diagnosed. Urea-clearances of infants in the first 14 days of life are far below those of adults when compared on the basis of surface area; on the whole the clearances probably vary with the minute volumes of the urine. The clearances approach adult level towards the end of the first year. These findings are supported histologically by the tall columnar cells which cover the glomerular tuft in fœtal life; these cells prove an effective barrier to ultrafiltration and are replaced by the thin pavement epithelium found in adult life. The excretion of diodone has recently been found to be very low in babies a few days old, and the creatinine clearances to be no higher than the inulin clearances. The ability to form and excrete ammonia, however, seems to be fully developed at birth.

Sodium, potassium, and chloride clearances are all lower in the infant, and especially the premature infant, an in the adult, which explains the premature infant's bility to œdema ; thus the premature infant should t be given much sodium chloride. The administration 0·9% saline as a source of fluid for a baby is bad erapy, since it presents the kidney with the task of creting a hypertonic solution—a task it can perform ly if the serum has already become grossly abnormal.

HIGH ALTITUDE IN THE TREATMENT OF TUBERCULOSIS

Dr. J. E. **Wolf** (Davos) regretted that the development of collapse therapy has led to a certain neglect of limatic treatment at altitudes of 4000–6000 feet. limatic treatment can plainly never completely replace urgical collapse therapy, particularly for the cavitating orm ; indeed high-altitude treatment increases the scope f surgery, since the patient may be made fit for collapse herapy by first having this conservative treatment. Recent statistics have shown the advantages of continuing both methods. Tuberculosis must be treated as a general disease with local manifestations. The mechanism by which high altitude helps to increase immunity is not clear: a mountain climate, though it stimulates body metabolism, also has a certain sedative action ; it has, moreover, a stimulating psychological effect.

Four climatic factors benefit the body's biological reactions: (1) diminution of atmospheric pressure ; (2) ultraviolet radiation ; (3) dryness of the air : and (4) diminution of the cooling power. The metabolism of respiration, circulation, and hæmopoiesis are certainly stimulated ; but there is evidence that pathologically increased metabolism—for example, in Graves's disease —is reduced at altitudes of 4000–6000 feet. Similarly the increased basal metabolism sometimes associated with tuberculosis is reduced at the same time as the increased blood-sedimentation rate and blood-globulin are lowered. It has also been shown that thyroxine injected into animals at high altitudes has only a quarter to a tenth of the effect that it has in the lowlands. The influence of altered vitamin metabolism must also be considered ; at high altitudes the blood-cholesterol increases, no doubt because of the intense ultraviolet radiation. When the blood-cholesterol rises there is an associated increase in the blood vitamin A. Both vitamins influence tuberculosis ; when vitamin A is deficient, the incidence of infection rises. At Davos it has been found in tuberculous patients that the blood vitamin A is decreased, the diminution varying with the gravity of the infection. It has also been shown that in the first few weeks after the change to a high altitude the vitamin A and D values increase together, even with cavitating disease, provided there is still a possibility of reaction. Some of the benefit from high altitude may be derived from its effect on the vegetative nervous system and from its encouragement of blood acidosis, in place of the alkalosis usually associated with tuberculosis.

The clinical results of high-altitude treatment have shown that it is strongly indicated in almost all forms of surgical tuberculosis. With pulmonary tuberculosis cases must be more carefully selected ; the treatment should not be adopted where the general condition is rossly impaired or the lung-area greatly reduced. All ther forms and stages of pulmonary tuberculosis are, enerally speaking, suitable for the treatment ; it is sometimes contended that the exudative forms should not e submitted to high altitudes, but in Dr. Wolf's view his is a mistake.

CELLULAR ADAPTATION TO EFFORT, ALTITUDE, AND OXYGEN DEFICIENCY

Prof. **Alfredo Vannotti** (Lausanne) pointed out that the effects of severe muscular effort and exposure to high altitudes are, in most respects, the same. The muscle persistently submitted to effort reacts by dilatation of reserve capillaries, the formation of anastomoses, and later possibly the formation of new capillaries ; this capillary adaptation is probably related to effort-acidosis. The myoglobin content in muscles submitted o 2–3 weeks' daily faradic stimulation is 10–35% more han in control muscles. It is now held that cellular espiration is regulated by two catalytic systems. One, made up of pigments based on hæmins, activates the arterial oxygen ; while the other is based on the activity of hydrogen transporters, the deshydrases, and is largely built up from the vitamins of the B group. With acute effort the muscle-content of dissociated iron increases, while with chronic effort there is a rise in muscle oxydase, myoglobin, and cytochrome C. With acute effort there is increased utilisation in the muscle of aneurine, riboflavine, and nicotinic acid ; but when hypertrophy ensues from chronic effort, there is a rise in the muscle content not only of myoglobin but of oxydase, cytochrome, active iron, and vitamins of the B group.

Ascent to high altitudes results immediately in a temporary increase in red blood corpuscles, attributed by Barcroft to splenic contraction ; then often the number of red cells falls rapidly, apparently through hæmolysis. Regeneration follows, with reticulocytosis and the formation of macrocytic red cells, rich in iron. Hæmoglobin and more especially myoglobin levels continually rise ; but whereas hæmoglobin has been observed to be formed with radioactive iron 6–8 days after injection, myoglobin and cytochrome are not synthesised with it until after 3–4 weeks. The organism's adaptation to high altitudes is thus slow ; the initial hæmolysis can be attributed to an attempt to mobilise iron for the rapid synthesis of cellular hæmins. With stay at high altitudes the spleen enlarges and there is some hypertrophy of the adrenals, especially of the adrenal cortex.

AMPUTATIONS

Mr. **George Perkins** (London) said that to satisfy the needs of the limb-maker it may be necessary to perform two operations—a provisional amputation followed later by a definitive one. The provisional amputation should be performed as low as possible, since the wound will probably not heal without infection ; there is no need to go above the level of existing infection. The technique does not differ from that in the definitive operation, except that the deep fascia and skin are not sutured. Healing is quicker if the skin-edges are sewn together for 2 cm. in the centre so as to cover the raw end of the bone ; but even this partial closure may not be safe with recent infection. For the definitive amputation primary healing should, ideally, be assured ; but it may be necessary to accept the risk of infection from a terminal ulcer. Experience from the first world war has shown that end-bearing stumps do not last ; the circulation in long stumps, moreover, often becomes defective. The sites of election now favoured by the Ministry of Pensions' surgeons are below or above the elbow, and below or above the knee. The short stump, though desirable, must be long enough to remain inside the socket of the prosthesis when the joint above is placed at a right-angle, and long enough to contain the insertion of the muscles that control the joint. A below-knee stump should measure 10–14 cm. from the knee-joint to the end of the tibia, and an above-knee stump 28 cm. from the top of the great trochanter to the end of the femur. At Roehampton the Syme amputation has been condemned, owing to the difficulty of fitting a comfortable prosthesis, which in any case is unwieldy compared with that fitted after a below-knee amputation. The optimum length for a below-elbow stump is 18 cm., measured from the tip of the olecranon to the end of the ulna, and for an above-elbow stump 20 cm., measured from the acromion process to the end of the humerus. The technique for definitive amputation is based on two considerations—the operation is performed by all manner of surgeons, and the needs of the limb-fitting surgeon must be met. The ideal criteria for the stump are : (1) the scar is not exposed to pressure ; (2) the scar is not adherent ; (3) the skin is not infolded ; (4) there is no redundant soft tissue ; (5) there is no projecting spur of bone ; (6) the stump is not tender ; and (7) the wound heals by first intention. After the operation the limb must be prepared to receive the prosthesis by shaping the stump, strengthening the muscles, regaining movement at the joint above, and reconnecting the brain to the stump. Finally, the patient must be taught to use the prosthesis.

CAROTID LIGATION IN INTRACRANIAL ANEURYSM

Prof. H. **Krayenbühl** (Zürich) emphasised the differences of opinion on the safety of carotid ligation. He has undertaken the operation in 35 patients, ligating in each case the common and internal carotid arteries, with more or less extensive periarterial sympathectomy ;

usually the artery has been compressed by hand for 20 minutes on the day before operation. Recurrent subarachnoid hæmorrhage has been the most common indication for operation. The results with infra- and supra-clinoid arteriovenous aneurysms have been uniformly good. Of 20 patients submitted to operation for bleeding supraclinoid saccular aneurysm, 6 died; among the 24 patients with saccular infra- and supra-clinoid aneurysm, postoperative flaccid hemiparesis has occurred in 4; but in 3 of these the disturbance has cleared almost completely.

PRIMITIVE TUBERCULOSIS, PRIMARY INFECTION, AND "PREMUNITION"

Prof. E. **Grasset** (Geneva) recalled that tuberculosis is seen in virgin stocks in its original uncomplicated forms. Primitive stocks may be attacked by acute infection at any age; indeed its spread may assume the form of an epidemic. Usually this type of infection results in early death. It may be spread by the lymphatic system from a primary focus in the lung; or the lymph-glands may be infected. In other patients the primary focus in the lung is the principal lesion, resulting in rapidly progressive pulmonary disease, and terminating in caseous bronchopneumonia or secondarily disseminated pneumonia. In some the spread of infection may be temporarily checked in the tracheobronchial lymph-glands. Pulmonary infection can be evaluated only by radiography; quite advanced lesions may be associated with few symptoms and no signs on auscultation, a good general condition, and a negative sputum. The lesion sometimes spreads through the lung in a compact mass; but it may spread rapidly in wide zones of one or more lobes. In children, and in some adults, the tracheobronchial lymph-glands are greatly enlarged, and the submaxillary and cervical glands may be grossly swollen and tender; in other cases all lymphatic glands are affected. After several weeks of this first phase, the infection enters a new and dramatic stage, with a gradual rise of temperature or sudden rigors and profound toxæmia. The picture becomes more clearly one of pulmonary infection, with cough and increasing expectoration; and a lobar or broncho-pneumonia may be simulated by the profuse, often bloodstained sputum, which, however, contains numerous tubercle bacilli. With rapid spread and cavitation, the condition deteriorates rapidly and the patient may die within 3 months, death often resulting from repeated or massive hæmoptysis and occasionally from meningitis. Necropsy shows that the lesions are mainly exudative with little or no fibrosis; in the same lung there may be different forms, such as massive caseous pneumonia in one lobe and fine nodules in the other. Elsewhere, as in the spleen, similar caseating lesions are found; and the larynx, pharynx, and intestinal tract may be ulcerated. This process is to some extent comparable to the juvenile type of infection seen after primary infection in some European children. In Europe today the acute, rapidly fatal, exudative type of lesion is unexpectedly common among the war-stricken populations. The best hope of control lies in "premunition" with B.C.G. vaccine or the vole-bacillus vaccine of Wells.

ARTERIAL INJURIES

Mr. J. J. **Mason Brown** (Edinburgh) divided arterial injuries into those that arise indirectly from a missile passing through nearby tissues, with arterial contusion and traumatic arterial spasm; and those in which the vessel is wounded directly by the projectile. The purpose of treatment is to restore the peripheral circulation, or, if this is impossible, to promote the development of a collateral circulation. Moreover, the limb must be so placed as to minimise the effects of ischæmia while the blood-supply is still depleted. The lumen may be restored by vein grafts or artificial cannulæ, followed by heparinisation. For success the circulation must be restored soon after the injury; later restoration may result in fulminating toxæmia through the absorption of products of disordered metabolism from the previously ischæmic limb. It should be realised that, though the peripheral pulses may be impalpable, there may still be sufficient flow of blood through the injured vessel to maintain the limb's nutrition until collateral circulation has developed. Primary surgery will abruptly interrupt the circulation; initial treatment should, wherever practicable, be conservative, to allow time for the development of collateral circulation, though a traumatic aneurysm often develops. The type of operation must depend on an assessment of the condition discovered at the operation; simultaneous ligation of the accompanying vein should be undertaken in primary surgery or in operations performed before the collateral circulation is established. Sympathectomy or sympathetic block, though of value in emergency ligations, is unnecessary when the collateral circulation is established. With false aneurysms hæmorrhage at operation should be controlled by a tourniquet; but in operations on aneurysmal varices no tourniquet should be used. When a tourniquet cannot be used it is important to gain control of the artery above and below the lesion. An intravenous drip should be set up before the operation is begun, and fresh blood should be at hand Secondary hæmorrhage, thanks to the sulphonamides and penicillin, is now a rare complication. After operation the limb should be placed about 6 in. below the heart-level and constricting bandages should be avoided; a sterile towel is a suitable covering. The limb can be exposed to room temperature. Venous stasis can be avoided by raising the head of the bed. Care of the skin is essential.

EXPERIMENTAL DIABETES MELLITUS

Prof. F. G. **Young**, D.SC. (London), said that the central problem of the cause of diabetes remains unsolved. The effects of pancreatectomy on carbohydrate metabolism are much more pronounced in carnivorous than non-carnivorous animals; the resultant diabetes can always be controlled by insulin. The influence of the pituitary gland is exerted largely by the secretions of its anterior part; but the posterior lobe also exerts a significant, though ill-defined, influence on carbohydrate metabolism. It is possible that the posterior pituitary secretion acts by influencing the secretions of the anterior part in the same way as adrenaline affects the adrenal cortical secretion. The diabetic condition in the dog during continued administration of anterior pituitary extract differs from that following pancreatectomy in that it is extremely unresponsive to insulin and is associated with increase in body-weight and nitrogen-retention moreover, the liver glycogen is high rather than low. There is experimental evidence of an antagonistic action between insulin and anterior pituitary extract. In dogs a permanent or so-called metahypophyseal diabetes has been produced by large amounts of anterior pituitary hormone; here irreparable damage is done to the insulin-secreting mechanism of the islets of Langerhans owing almost certainly to over-work under the influence of the pituitary extract. The growth-promoting factor of the anterior pituitary also inhibits carbohydrate oxidation Diabetes can be produced by the intravenous injection of alloxan, which causes acute necrosis of the islets of Langerhans, possibly through over-work exhaustion. Dietetic experiments suggest that the major cause of diabetic ketosis is a high-protein intake of meat rather than fat. Anterior pituitary extract occasionally stimulates regeneration of the insulin-secreting cells, but it is not yet possible to apply this therapeutically. The effect of œstrogen has been tried, in view of its known capacity to depress the gonadotropic factors of the anterior pituitary; œstrogen is, in fact, effective in alleviating postmenopausal diabetes, but there is no evidence that it exerts a direct action or that the action is mediated by the anterior pituitary.

Human diabetes is not a single syndrome with one cause. Some hold that the diabetic diathesis is inherited as a recessive mendelian character, and that the incidence of the condition has risen since the latent islet defect was revealed, because of the opportunities for consistent over-eating under conditions of modern civilisation. The anterior pituitary is almost certainly concerned in the origin of some cases; under certain conditions other glands, including the adrenals and the thyroid, may be implicated.

EXPERIMENTAL RADIOTHERAPEUTICS

Dr. J. S. **Mitchell** (Cambridge) ascribed recent additions to our knowledge of the therapeutic action of X and gamma radiations largely to the influence of cytology and cytochemistry, genetics, and radioactive tracer methods. There is now a better understanding of the ignificance of chromosome breakage and of the dependence of the biological efficiency of different radiations on specific ionisation. The therapeutic possibilities of high-energy (20–50 Mev) beta and gamma radiations in the treatment of cancer and related diseases should be more closely examined. At present the 30 Mev betatron appears to be the most suitable instrument for application in radiotherapy as a source of high-energy gamma radiation. The advances which led to the atomic bomb provide a new way of preparing large amounts of radioactive isotopes which should become widely used in medicine as: (1) radioactive tracers for the study of metabolic processes and in pharmacological investigations: (2) artificial gamma-ray sources in radiotherapy; and (3) agents such as P^{32} and I^{131} with therapeutic possibilities depending on the selective concentration of the radioactivity of suitable isotopes in particular cells and tissues. Hevesy, using radiophosphorus (P^{32}) as a tracer, showed that the synthesis of thymonucleic acid is inhibited by therapeutic doses of X irradiation, thus providing convincing confirmation of previous work using ultraviolet photomicrography, and the Feulgen reaction. Great caution must be exercised before any radioactive material is introduced into patients on account of the possible risk of long-term deleterious effects. The most promising substitute for adium is now thought to be radiocobalt (Co^{60}), with a half-life of 5·3 years. Of the selectively absorbed adioactive isotopes, P^{32} and I^{131} may prove the most useful in therapeutics: interesting results have been reported with P^{32} in the palliative treatment of chronic myeloid and lymphatic leukæmia and lymphosarcoma, and in polycythæmia. The value of fast neutron beam therapy in cancer and allied diseases is still an open question; evidence is accumulating to indicate that the biological action of fast neutrons differs in some ways from that of X and gamma radiations.

NATIONAL HEALTH SERVICE

A SPEECH BY MR. BEVAN

ADDRESSING the Society of Medical Officers of Health at their annual luncheon in London on Sept. 20, Mr. ANEURIN BEVAN, Minister of Health, said that though the armies were still arrayed on the battlefield of the National Health Service Bill they were becoming, he hoped, increasingly listless. All must unite to carry out whatever Parliament finally decided; any other course was anarchy. When the Bill became law the main task would begin—the administrative task, so much harder than the legislative. It would be impossible to frame regulations properly without the help of representatives of the various branches of the medical profession. His own purpose had been to follow with fidelity Lord Dawson's principle—to create an apparatus of medicine and leave the profession to exercise it in freedom and independence. Parliament must create the apparatus but it was for the profession to decide how to use it.

By medical officers of health, Mr. Bevan continued, the Bill had been criticised because it put hospital midwifery under the regional hospital boards while domiciliary midwifery remained under the *local authority* —an arrangement described as dichotomy. But all the serious difficulties of incoördination in the past had arisen because the hospitals had been owned by different groups. Doctors would in future move quite freely between hospitals and clinics. The M.O.H. and the hospital doctor must in future join fully in their work, having no occasion for jealousy. The unity of the scheme was determined by the right of the individual citizen to the use of all services of whatever kind, and the difficulties raised, which were theoretical and slightly pedantic, would in practice fall to the ground. "We are now facing," said Mr. Bevan, "a very critical year," and he wanted to make all possible use of the great experience of health workers. One of the great dangers was over-centralisation, and the more decentralisation could be arranged, the better for the service.

In conclusion the Minister defied anyone to point to any country more ambitiously striving to raise the standards of life of the citizen. In every direction there was in this country a renaissance. "I believe that we shall win our way through, but there is a frightful shortage of every kind of worker." This shortage made it essential to have complete coöperation between all engaged in the same task, and he appealed to medical officers of health as experts in that kind of coöperation.

Replying as president to Mr. Bevan's toast of The Society, Prof. J. JOHNSTONE JERVIS (Leeds) said that the Bill was not perfect: no legal instrument was perfect. Nevertheless it was incontestably the greatest thing that had been done in social medicine in any age or country. It should be given a fair chance to justify itself, and nothing was to be gained by adopting a hostile attitude. "We and our colleagues may be relied upon to play the part allotted to us in an earnest desire to carry it to a successful issue." On the eve of his retirement, however, Prof. Johnstone Jervis wished to pay a tribute to "a very great English institution"—local government. And he could not but deplore the present tendency of Government departments to encroach on the province of local authorities, the latest example being in the National Health Service Bill. If the health services of this country had today attained a high degree of perfection the credit was largely due to the inspiration, enterprise, and hard work of local authorities. Local government was the keystone of the arch of democracy. However good and effective might be the new authorities set up under the Bill, they could not replace the present local authorities, and he prophesied that in the course of years they would be replaced by local authorities purged of their imperfections. If he might presume to advise the Minister—head of what was once the Local Government Board—it would be to expand, strengthen, and maintain the powers of local government.

SCHOOLING FOR THE SUBNORMAL CHILD

WHAT CAN BE DONE

HANDICAPPED children need favourable conditions if they are to develop their abilities to the full. Special schools provide for children with serious disabilities, but for others special arrangements must be made in ordinary schools. In answer to the questions often asked by authorities who have to make such arrangements, the Ministry of Education have published a useful pamphlet[1] explaining what kinds of children need special educational treatment, how they should be selected, the probable numbers, and the results to be expected, besides giving advice on the arrangement of classes and the qualifications of teachers.

PHYSICAL DEFECTS

Children who may need special treatment are the blind (0·2–0·3 per 1000 pupils) or partly sighted (1 per 1000), the deaf (0·7–1 per 1000) or partly deaf (1 per 1000 upwards), the delicate (1–2%), the diabetic, the educationally subnormal (10%), the epileptic (0·2 per 1000), the maladjusted (about 1%), the physically handicapped (5–8 per 1000), and those with speech defects (1·5–3%).

At any time after the child is two years old the parents may ask to have him examined to see whether he is going to need special educational treatment; the authority is bound to have this done, and to provide special education if the child needs it and the parents wish it. The child need not be attending any school when the request is made. In some cases the earlier special treatment or training is begun the better. Many blind and deaf children between 2 and 5 are already in nursery schools or departments for the blind or deaf, and the decrease of crippling among children of school age is largely due to orthopædic treatment given in the early years. Children seriously disabled by blindness, deafness, epilepsy, aphasia, or physical handicaps can always be given places in special schools. Partly sighted children, if they can benefit from ordinary classes in primary or secondary schools, or in open-air schools, should sit at the front in a good light, and use extra-large paper and soft black pencils. Experiments on lenses to magnify ordinary print are now being made. Many partly deaf children can be given a chance in ordinary schools for six months to a year; if they fail to follow what is said in ordinary school situations and if their own enunciation is not clear and fails to improve they can then go to a special school. Advice on their progress should be sought from an educational clinic for the deaf, or from the nearest deaf school. The education authority should provide courses in lip-reading, and if necessary in speech improvement, for such children, who may be collected for the purpose in groups of 5–10 for an hour twice weekly. Where no teacher can be found for a class such children may perhaps be sent for a term to a boarding-school for the partly deaf, to take an intensive course in lip-reading.

---

[1] Special Educational Treatment. Ministry of Education Pamphlet no. 5. H.M. Stationery Office. Pp. 36. 9d.

Delicate children may need to rest on a stretcher-bed during the lunch-hour. Diabetic children, it is suggested, should live in hostels, under medical and nursing supervision, where their diet can be regulated and they can be taught the reasons for the restrictions placed on it; teachers could report at once to the hostel if a child developed symptoms in school. Large authorities and voluntary bodies are asked to establish such hostels. Aphasic children are rare, but need special schooling; at present they usually have to go to deaf schools for lack of a more suitable place. Children with speech defects should attend classes twice a week, held by a speech therapist working in the school health service.

THE BACKWARD

By far the largest problem is presented by educationally subnormal children, who form 10% of the school population. Under the new Education Act it is not necessary to decide what has caused a child to be backward before giving him educational treatment: that can be discovered during the process of educating him. Children with an intelligence quotient below 55 cannot be educated at an ordinary school; and backward children who are detrimental to the education of others in the class should not be retained on sentimental grounds, but should go to special schools. Thus a steady stable child with an intelligence quotient of 70 may get on all right in the ordinary class, while a nervous child of similar grade might be better with the support of a special school. If there are enough subnormal children in the school they may be grouped in a class; or a class drawn from a group of schools might be arranged, under a teacher who believes in the value of the work.

The maladjusted child of normal intelligence needs the help of the child-guidance team, and local authorities should therefore make proper child-guidance arrangements, or at all events employ an educational psychologist. Sometimes a child can continue to go to his own school while attending the child-guidance centre, or sometimes he will profit by a fresh start in a neighbouring school. Others, whose maladjustment arises in the home, may need to be boarded out with foster parents, or grouped in hostels while still attending ordinary schools. Others again may benefit most from a boarding-school for maladjusted children. Day schools for such children have been established in at least two areas, and have given promising results.

THE TEACHER

The pamphlet ends with a clear-sighted note on the qualities to be sought in teachers of children needing special education. They must not undertake the work to indulge their own maternal and compassionate feelings. The life of the handicapped is hard, and these children must be helped to be self-reliant, optimistic, hard-working, and as far as possible skilled. Their teachers must bring them emotional normality as a pattern, and must be capable of making the most of each child's abilities.

MR. T. F. DIXON, PH.D., has been appointed professor of biochemistry in the Royal College of Medicine, Bagdad.

MODELS OF THE FOOT.—The Foot Health Educational Bureau has prepared a series of models of healthy feet at all ages from infancy to the adult, and is prepared to supply casts of these at a reasonable cost. They are likely to be of considerable value as visible standards of the normal to those concerned with the preventive care of the feet—doctors and nurses in child-welfare clinics and factory health services, physiotherapists, physical training experts, and others to whom the earliest stages of foot deformity are the most important. The address of the bureau is 90, Ebury Street, London, S.W.1.

In England Now

A Running Commentary by Peripatetic Correspondent

PERHAPS this business of German measles in the third month of pregnancy being related to congenital defect which are common but fail to be obvious because o the lapse of time between the initial and consequent conditions. With a view to scooping a Nobel prize with an original generalisation on these lines, I composed myself for half an hour's research in my armchair. It was logical, I thought, to assume that the greater the time interval, the more likely would it be for a Great Generalisation to be missed. So I began by looking for adult disorders originating from events in infancy. I chucked this line of thought when it dawned on me after five minutes that much of the field had already been scooped by a bloke called Freud. After a few seconds of despondency my courage returned. I would out-Freud Freud. I would go further back still.

Picture if you can an ovum, a fresh and blooming débutante making her one and only appearance in utero. Alas, however, she differs from other protozoa in that she cannot split in the middle on her own and can only achieve immortality by the sacrifice of her unicellularity. Her chances of doing this are limited to the next forty-eight hours or so. If she has no spermatozoic suitors in that time, then she's had it. Now picture if you can an ovum in her forty-seventh hour. Her protoplasm is pickled, her genes are jiggered, her mitochondria are moth-eaten, and her cell-membranes are slipping up. Altogether, as far as ova go, she's a hag. Then suddenly there is a lashing of tails in the middle distance and a crowd of the boys come charging up the slope. She gasps with relief. She shrieks with joy. She grasps the winner by the scruff of his neck before he can have a chance to see what he's landed with and change his mind. Perhaps it is in such a union that originate those placebos and excuses which are yet undeniable truths—the "constitutional weakness," the "constitutional instability," the "constitutional predisposition."

Yes—I suppose it is rather far-fetched. And anyway, —don't you have to make a speech in German when they give you a Nobel prize? Awful fag having to learn German just for that.

* * *

The outstanding impression from last week's conference in Basle is the kindliness of our Swiss hosts, springing from a keen sense of kinship. There are other memories: a drive along the road, divided only by the Rhine, to Rheinfelden, where Dr. Donald Hunter, somewh incongruously, spoke of industrial medicine; the clean ness of Swiss towns; the well-stocked shops; t 40-million-franc hospital, constructed during the wa and containing gadgets enough to delight a schoolbo mind for weeks; and the food. To most, the meal after Britain's austerity and unpolished cuisinerie, wa a natural attraction, though Switzerland, with tw meatless days a week and noticeable shortages in milk grain, and sugar, is not the land of superabundance whicl some have painted. There is, moreover, no excess o consumer goods, and those who plotted to carry off such treasures as coloured china found their way barred. I was pleasing to see in the shops many articles bran "*Made in England*," even though many of them are still unobtainable here. Visitors who did go shopping found some difficulty in distinguishing the 5 and 10 centime coins from the half-franc; the difference in texture and the serrated edge of the half-franc piece was little help to the uninitiated. Incidentally, why does Britain alone still adhere to the vast penny for a piece of such small denomination? Despite the smallness of the country, the dialect differs enormously between different places. In Zürich diction is rapid and clipped, while in Berne, as befits the centre of a large rural area, it is slow and sing-song. In Basle the speech is noticeably more elegant, and among the Swiss people the town has a reputation for mordant wit of which other cities stand in awe. But the canton spirit is strong, and the feeling is perhaps no deeper than that between Liverpool and Manchester or between Glasgow and Edinburgh. Certainly in Basle, as elsewhere, the visitor finds nothing but friendliness.

As, with regret, we turned our minds to packing for the homeward journey, we discussed with nervous trepidation the ways of British Customs officials. There were, we found, two schools of thought: according to one, they were wise men with all-seeing eyes, from which naught could be hid; the other contended that the Customs was fair game, and that much could be concealed by the wary traveller. As to which school I heeded—that concerns only myself and my bank manager.

* * *

The Very Senior Medical Officer (V.S.M.O.) was annoyed. One of the station medical officers under his jurisdiction had sent in a submission that married female auxiliaries were securing early release from the Service on the grounds of pregnancy when it was impossible to confirm or refute their claims on clinical grounds alone. The station medical officer contended that the certificates given by the private doctors of these women were valueless so early in pregnancy unless backed by biological tests, and that in any case such early discharge from the Service was not justified at a time of acute woman-power shortage. The V.S.M.O. did not agree; and he did not like the station medical officer. Perhaps his annoyance made him careless. He sent for the relevant orders and after consulting them wrote a minute: "I think that the provisions of Order XYZ are adequate to deal with these cases." The papers passed to the next staff officer, who took the trouble to verify the order reference and then, with a gleam in his eye, wrote that so far as he knew the apparatus mentioned in Order XYZ had never positively been implicated in these cases. When the V.S.M.O. received the papers back he sent again for the orders to find that he should have written "Order XZY" and not "Order XYZ," which bore the full title of *Portable Aiming Teacher*.

It was the twenty-third time that I had resolved to take up the piano seriously, but the first such occasion on which I realised why it is that concert pianists are invariably portrayed as highly strung, egocentric, temperamental, and generally difficult individuals. It is all a matter of hysterical dissociation. The essential of pianoforte technique is that the falx cerebri should act as an iron curtain, preventing one half of the brain knowing or caring too much about what is going on at the other side. My left hand knows all too well what my right hand is doing—and vice versa. Nor are they satisfied with each other's performance. Each is continually saying to the other, "No, my dear! This is how you should do it." Hence the chord-salad. But take a gross hysteric and put her at a piano. If she has the rudiments then the rest comes just as easily and much more pleasantly than automatic writing. Her bass and treble selves enjoy a glorious independence but watch each other sufficiently out of the corners of their eyes to avoid the effect of a completely split personality.

Tschaikovsky had to conduct clutching his beard for fear his head fell off. If I ever began to become at all proficient at the pianoforte my main preoccupation would be lest my cerebral hemispheres suddenly fell apart. However, I can shelve that worry till the twenty-fourth time.

* * *

The labels on the exhibits at the *Britain Can Make It* exhibition at the Victoria and Albert Museum omit the final despairing cry of the plum-stone prophecy, though they still tantalise the would-be purchaser with their degrees of availability—now, soon, later. All the same it will be worth waiting to have a kitchen tap whose washer can be changed without cutting off the water at the main, or a pair of transparent plastic slippers that will make Cinderella's look like clogs, or an electric toaster that even King Alfred could use. But life in the brave new world will have its own complexities. The ingenious combined stepladder, ironing board, and baby chair, for instance, may set as many problems as it solves, and it would take an experienced sleeper to attempt a night in the air-conditioned bed of the future with its dashboard for automatic temperature control. Twenty-four model rooms show us the homes, schoolrooms and offices of the future, and Mr. Nicolas Bentley's sketches introduce us to their inmates with such convincing detail that we find ourselves congratulating the railway engineer (formerly in the 8th Army and has a houseproud wife and five children), the young doctor (newly set up in practice, but studies social conditions and has a wife who likes outdoor sports and photography), and the middle-aged storeroom clerk (collects stamps, reads thrillers, and is a regular picture-goer) on having solved their housing problems so satisfactorily.

A radio speaker with a persistent cough can be infuriating to his audience, but they can always switch him off. The situation is much worse for the speaker himself; when he feels a tickling sensation starting in his throat he must go on speaking into the microphone, keep at the correct speed which has been thoroughly impressed on him at the rehearsal, follow his script, and all the time wonder just when the explosion will come. There is a switch on the table marked "Censor" which puts the speaker off the air. I had always imagined it was for interrupting anyone who transgressed the B.B.C. code and inserted a bawdy remark, but I now discover it is for the benefit of the cougher. He pauses at a suitable spot, presses the key, clears his throat satisfactorily, lets go the key, and proceeds hoping that the public is none the wiser. I do not like this technique myself, and having recently to broadcast with an irritating and persistent cough I relied on "syrup codein. phosph." This completely stopped the coughing and I strongly recommend it to others who are too frightened to use the censor switch.

Public Health

Standardisation of Death-rates

THE issue of the civil tables[1] completes, with the previous publication of the medical tables,[2] the Registrar-General's report on 1941. This was one of the most depressing years of the war and some of its depression is reflected in the figures: thus the birth-rate at 13·9 per 1000 was the lowest ever recorded, while the infant mortality of 60 per 1000 related live births was higher than any since 1933. To statisticians and medical officers of health, however, perhaps the main interest of the medical section lies in the introduction of the new method of standardising death-rates.

It has been customary to standardise the crude death-rate in order to take into account the change in the age-structure of the population by applying the age-specific death-rates in the year under review to the standard population of England and Wales in 1901. The use of such a standard population ensured that, in a comparison between two standardised death-rates, the differential effect of ageing of the population on the crude death-rate was neutralised; the influence of other agencies, such as epidemic and therapeutic innovations, on mortality was thus readily isolated. Unfortunately there are some residual difficulties even with this method. In long-range comparisons, for example, the rate of decline in the standardised death-rate will depend upon the actual population used as a standard: thus the decline in mortality from 1901 to 1939 may appear either as 50% if 1901 is used as a standard, or 38% if 1939 is used as the standard population. Similarly in comparing the mortality in more recent years, say between 1938 and 1939, even reversals of the trend of the standardised death-rate can be produced by changing the standard population from 1901 to 1939. It would be more realistic therefore in making such comparisons to use a modern population.

To combine this realism with some balancing of the divergent weighting effects of the population being examined and this new standard, it is proposed to calculate in future the comparative mortality index. The last available stable modern population—that of 1938—is used as one standard reference basis, the other being the particular year under review. The new standard population is made up by averaging, in each age and sex group, the numbers in each of these two populations so as to get a new standard midway between them. To

---

1. Registrar-General's Statistical Review of England and Wales for the Year 1941. Tables. Part II. Civil. H.M. Stationery Office. 1s.
2. Tables. Part I. Medical. H.M. Stationery Office. 5s.

this intermediate type of population are then applied the death-rates at ages of (*a*) the given year, and (*b*) 1938, to obtain by adding over the whole age scale the total number of expected deaths in this new standard population at these death-rates. The ratio of the expected deaths in the standard population at the death-rates of the given year to the similar total for the 1938 rates gives the comparative mortality index or C.M.I. The C.M.I. for any year can be compared with the previous one by dividing the former by the latter to obtain a "mortality ratio." Similarly a comparison between the standardised mortality for males and females, based on the average number of both exposed to risk, is given by the "male-female ratio." In this and succeeding reports these various indices and ratios will be given for long series of years so that the trends in mortality can be easily followed.

There are good reasons for these innovations, though they will doubtless cause acute headaches to D.P.H. students. Their practical value should become evident in future reports.

Infectious Disease in England and Wales

WEEK ENDED SEPT. 14

Notifications.—Smallpox, 0; scarlet fever, 791; whooping-cough, 1744; diphtheria, 255; paratyphoid, 33; typhoid, 17; measles (excluding rubella), 1213; pneumonia (primary or influenzal), 284; cerebrospinal fever, 28; poliomyelitis, 22; polio-encephalitis, 1; encephalitis lethargica, 1; dysentery, 68; puerperal pyrexia, 100; ophthalmia neonatorum, 75. No case of cholera, plague, or typhus was notified during the week.

The number of service and civilian sick in the Infectious Hospitals of the London County Council on Sept. 11 was 861. During the previous week the following cases were admitted: scarlet fever, 62; diphtheria, 20; measles, 20; whooping-cough, 45.

Deaths.—In 126 great towns there were no deaths from scarlet fever, 1 (0) from an enteric fever, 3 (1) from measles, 10 (1) from whooping-cough, 5 (0) from diphtheria, 54 (3) from diarrhœa and enteritis under two years, and 2 (0) from influenza. The figures in parentheses are those for London itself.

Swindon reported the fatal case of an enteric fever. Liverpool had 3 deaths from whooping-cough and 7 from diarrhœa and enteritis.

The number of stillbirths notified during the week was 243 (corresponding to a rate of 26 per thousand total births), including 37 in London.

Medicine and the Law

The Nature of a Charity

A LEGAL training undoubtedly helps judges to decide an issue; but it may be a hindrance when they are obliged first to agree on what they are there to decide. In the case between the Commissioners of Inland Revenue and the National Anti-Vivisection Society, now published by the Research Defence Society,[1] it was agreed at every hearing that the benefits to men and animals of animal experiments have been great, and that the suppression of such experiments would end medical and scientific advances in many directions: but was this relevant? The society had claimed exemption from income-tax on the ground that they were a charitable body; and the commissioners had refused the claim on the ground that the society were not such a body.

A meeting of the Special Commissioners of Income Tax was held in December, 1943, to hear evidence from both sides for the purpose of an appeal to the High Court. Publications of the society were considered, and evidence was given by their director, Dr. R. Fielding-Ould. Testimony on the value of animal experiments was then taken from Major-General L. T. Poole, Sir Edward Mellanby, Dr. R. D. Lawrence, and half a dozen other medical authorities. In their decision, the commissioners, after discussing the possible benefit to morals and education from the society's efforts to abolish vivisection, declared that

> "... if we conceived it to be our function to determine the case on the footing of weighing against that assumed benefit the evidence given before us, and of forming a conclusion whether, on balance, the object of the society was for the public benefit, we should hold, on that evidence, that any assumed public benefit in the direction of the advancement of morals and education was far outweighed by the detriment to medical science and research and consequently to the public health which would result if the society succeeded in achieving its object, and that, on balance, the object of the society, so far from being for the public benefit, was gravely injurious thereto, with the result that the society could not be regarded as a charity."

But in 1895 two forerunners of the society were held (*In re Foveaux*) to be a charity within the legal definition of the word, and this finding—by Mr. Justice Chitty, as he was then—had never been overruled. The commissioners therefore decided that they were bound by the authorities to hold that the society were a charitable body, and to allow their claim.

When the case was heard in the High Court, however, in July, 1945, Mr. Justice Macnaghten held that the evidence proved that the society's main object was the total abolition of vivisection, and that "attainment of that object, so far from being beneficial, would be gravely injurious to the community." He therefore allowed the appeal of the revenue authorities, whereupon the society took the case to the Court of Appeal.

At the hearing in this court, in December, 1945, the judges disagreed. The Master of the Rolls held, with Mr. Justice Chitty in the case cited, that prevention of cruelty to animals is a charitable object, and that the society existed for the purpose of preventing a particular form of cruelty, namely vivisection.

> "... kindness and love towards animals," he said, "are virtues the cultivation of which is conducive to the moral advancement of humanity. I should be ashamed to hold otherwise. The proposition is not made untrue by the fact that human weakness or urgent human need persuades or compels individuals or the community at large to sacrifice the moral benefit. ... I should not care to find myself having to argue with anyone who regarded the practice of operations on living animals as anything better than a lamentable necessity."

In short, the moral value does not disappear merely because humanity has benefited by animal experiments, or because the end is thought to justify the means. He was for allowing the society's appeal.

Lord Justice MacKinnon took the opposite view. He felt that in 1895 Mr. Justice Chitty had failed to decide the very issue before him—"Has it been proved to me, by the evidence to which I have listened, that the purposes of these [two anti-vivisection] societies are beneficial to the community?" Though he held that "to be a charity there must be some public purpose, something tending to the benefit of the community," yet, when he came to give judgment, he said: "The intention [of these societies] is to benefit the community: whether, if they achieved their object, the community would in fact be benefited is a question on which I think the Court is not required to express an opinion." With this Lord Justice MacKinnon could not agree. The intentions of those who support such societies may indeed be charitable:

> "I readily assume that the motive which leads old women to make bequests to this society is concern for the dear dogs. As one who has more than once experienced the grief of losing a beloved spaniel, I can respect and applaud the motive: though I do not think my respect and applause can be expected when it becomes a matter of the dear guineapigs and the dear rats."

But the motive of those who provide the money is immaterial, since the opinion of a donor that a gift is for the public benefit does not make it so in law. He felt that, on Mr. Justice Chitty's reasoning, a society seeking to make the sale of rat-traps illegal, or a society designed to prohibit the sale of insecticides, would be equally charitable. He supported Mr. Justice Macnaghten's ruling, and thought the society's appeal should be dismissed with costs, a view with which Lord Justice Tucker agreed.

The appeal of the society was dismissed with costs, but they were given leave to appeal to the House of Lords. This final appeal has been lodged, but its date has not yet been fixed.

Letters to the Editor

DISCREPANT SALARIES

SIR,—I read with amazement the five advertisements rom the Middlesex County Council in your issue of ept. 14. In the three for physicians and one for a surgeon t general and tuberculosis hospitals the salary rose to 1800 and then to £2200 as a special grade. The other dvertisement was for a deputy medical superintendent n a mental hospital and the maximum was £850; yet he applicants for all the posts will be, or should be, of bout the same professional standing.

Every effort is now being made to unite psychiatry nd general medicine, but one of the essentials is an nlightened outlook on the part of employing authorities. When a county council which normally has a progressive nedical policy can only assess the value of the brain at ess than half that of the body surely something must be very wrong?

Netherne Hospital, Coulsdon, Surrey. E. CUNNINGHAM DAX.

RELATIONSHIP BETWEEN PRIMARY AND ADULT PULMONARY TUBERCULOSIS

SIR,—The disparagement of morbid-anatomical findings at the Tuberculosis Association's meeting (*Lancet*, Sept. 14, p. 382) cannot, I feel, be allowed to pass without comment. While it is true that a few odd post-mortem examinations, however carefully conducted, cannot solve the problem of the origin of phthisis, it is by morbid-anatomical research, and by it alone, that the actual changes initiating phthisis and their relationship to preceding tuberculous changes, can be demonstrated. Epidemiological and radiological surveys consciously or unconsciously refer to these changes and are of necessity based on their study and knowledge. There can therefore be no question of one method of approach being more "reliable" than the other or superior to it because of the larger number of suitable cases. The two methods are *complementary*.

Phthisis appears to develop from the primary lesion either within a *short* interval, by direct bronchogenic spread from a softening primary focus ("primary cavity"), or from small "subprimary" (probably blood-borne) foci, or else, after a *long* interval, by recrudescence. The former, more acute, development is usually seen in young adults, whereas recrudescence is observed in the elderly or middle-aged in whom a calcified (primary or early postprimary) focus may be found in a state of "atheromatous liquefaction" causing decomposition of the calcified material and a break-through into adjacent bronchi. It is the subsequent caseous bronchitis which in this type provides the "prephthisical" focus.

Central Middlesex County Hospital,
London, N.W.10. WALTER PAGEL.

GOOSE-SKIN REFLEX IN MALNUTRITION

SIR,—When I visited the orthopædic hospital at Siglap, Singapore, to study various signs of malnutrition, Captain D. J. D. Bell, who was in charge of the hospital, showed me a boy, aged about 10 years, in whom a goose-skin reflex of the abdomen could be produced. The boy had signs of riboflavine deficiency (circumcorneal proliferation of the capillaries and an enlarged magenta tongue), muscular weakness, and other somewhat indefinite signs of mild nerve degeneration, suggesting early beriberi. The skin of the abdomen appeared normal and felt smooth, and no enlarged glands could be seen raised above the surface; but, when the blunt end of a pencil or a finger-nail was drawn lightly over the skin, within a second or two there was well-marked goose skin. The glandular papules did not all appear at once but came up, a few at a time, in two or three seconds. In about half a minute the goose skin started to disappear, the papules fading away more or less in the order in which they had appeared. The skin of the other parts of the body did not show this phenomenon.

I have examined for this sign 111 hospital patients with various diseases. Among them were 14 cases of beriberi in men; in 3 of them the sign was positive. These 3 were early cases; all had mild paresis, and there was pain on pressure of the calves in 2 of them. The 11 negative cases were in later stages of beriberi, and only 1 of these had pain on pressure of the calves. I have found the sign in only 1 other case among these patients, a man with mild spastic paraplegia. This paraplegia was of much the same type as lathyrism and therefore probably of dietary origin due to deficiency of vitamins, aggravated by some toxic substance in the food. In support of this was the fact that his 9-year-old son was lying in the next bed with a more advanced spastic paraplegia. The son did not show the goose-skin reflex. Of the 5 patients showing this sign, all had one or more signs of deficiency of riboflavine, all had swollen fissured magenta tongues indented by the teeth, 2 had patches of superficial erosion of the tongue, and 3 had well-marked circumcorneal injection.

Beriberi is characterised by peripheral neuritis and various degrees of degeneration of other parts of the nervous system. The goose-skin reflex must be due to degeneration of the posterior part of the spinal cord; it cannot be due to peripheral neuritis.

The 3 adults with beriberi had patches of hyperkeratosis follicularis on the abdomen, but only a small proportion of the glands were affected, and these papular enlarged glands remained unaltered when the goose-skin reflex was produced in the unaffected glands.

The only other patients with lesions of the nervous system who have been examined for this sign were 2 with hemiplegia, but the reflex was not elicited.

Fulbourn, Cambs. LUCIUS NICHOLLS.

EFFECT OF PHOSPHATE ON CARBOHYDRATE ABSORPTION IN SPRUE

SIR,—Dr. Stannus (Sept. 21, p. 436) has misinterpreted our intentions. In our preliminary communication (1945, ii, 635) we gave details of experimental results which indicated that there was an upset in intestinal phosphorylation in sprue. In such short communications reviews of the literature are out of place and only essential references should be given. We referred to Verzar, whose pioneer work on phosphorylation was the basis of our research. The idea that intestinal phosphorylation might be retarded in sprue was not new when Dr. Stannus published his interesting essay on the disease. We found it already suggested in the extensive publications of Verzar and his colleagues[1] and in the more recent review on the ætiology of sprue by Leitner.[2] All these works were published before Dr. Stannus's paper.[3]

School of Tropical Medicine,
University of Liverpool. BRIAN MAEGRAITH.

PATENT MEDICINES

SIR,—Your leading article of August 24 discusses an old yet ever topical subject. Few will dispute the reasonableness of most of Mr. Linstead's "indictments," but the remedies he offers are somewhat cumbersome. To set up a new Whitehall machinery, with registers, boards, fees, collectors, &c., would put new burdens on the community without achieving the desired results. I suggest that the first aim should be to confine the sale of "patent" medicines to qualified chemists. The pharmacist is a trained person who knows when to refuse a ready-made medicine and when to tell a customer to seek a doctor's advice. One of the main rules of the Chemists' Friends Association, which you mention, is that proprietary remedies of its manufacturer members can be supplied only through qualified chemists. If the medical profession would give a helpful hand to an association such as this, only good could result—without official interference.

Gerrards Cross. S. BROOK.

WOMEN IN MEDICINE

SIR,—In regard to the proportion of women doctors remaining in practice, the figures quoted in your Students' Guide (August 31, p. 307) are misleading. The survey by the Medical Women's Federation was taken in 1944, at which time, I understood, all able-bodied women between certain ages were obliged to work full-time (or part-time if home ties were too great). Only those with full-time home duties were exempt.

London, S.W.12. VIVIAN M. USBORNE.

PERNICIOUS ANÆMIA AND CARCINOMA OF THE ŒSOPHAGUS

SIR,—Nineteen years after the death sentence in pernicious anæmia (P.A.) was commuted to "liver for life" it is now becoming generally recognised that the patient with P.A. is more liable to gastric carcinoma than is his healthy neighbour.[1] The best examples of this concurrence seen here in the past few years were (1) a man with P.A. diagnosed by blood-count, barium meal, test-meal, &c., in July, 1938, who died, aged 37, in September, 1943, three months after laparotomy had revealed inoperable gastric carcinoma; and (2) a woman, first admitted to hospital with P.A. in October, 1933, who died in September, 1942, at the age of 39, after a short history of gastric upset; her neoplasm was proved by necropsy and histology. These two patients were considerably younger than in most of the recorded cases.

I have not been able to find any record of œsophageal cancer in a patient with P.A., and the following presumptive case is reported in the hope that others may look out for such cases.

A man, aged 49, was first sent to this department on March 31, 1938, by Dr. H. T. Cank, of Leyland, for a blood-count. He had had pneumonia in 1932 and 1933, and several attacks of "influenza" since, the last being a few weeks ago and attended by pain suggesting pleurisy. He had long been easily tired, had lost weight, and had recently noted soreness of the tip of his tongue.

His brother was known to the department as a case of P.A., having attended regularly since August 1, 1935, when he was 32 years old. Otherwise the family history was clear of anæmia and cancer.

Apart from clinical anæmia, physical examination was negative. Blood-count showed red cells 2,500,000 per c.mm., Hb 70% (Haldane), C.I. 1·4; white cells 7200 per c.mm. (differential count normal). The mean red-cell diameter was 8·2 μ (halometer).

After treatment with 'Campolon' the blood became normal by April 27, 1938. On a dose of 2 c.cm. every three or four weeks, blood-counts were normal in March and July, 1939. Patient was seen once in 1940, thrice in 1941, and the figures were normal in four counts in 1942 and three counts in 1943, when 'Anahæmin' was being given. A test-meal in November, 1941, showed a histamine-fast achlorhydria. In January, 1943, patient was in hospital for four weeks with a left lobar pneumonia. *He left hospital 17 lb. heavier than on admission.*

On Jan. 5, 1944, he was readmitted, complaining that for three months he had been regurgitating food about an hour after eating, and that for six weeks he had felt food stick at about the level of the mid-length of the sternum. Despite a good appetite he had lost much weight, and he had sternal pain radiating to the right axilla.

He was wasted, and the right pupil was larger than the left. Blood-count was normal. Radiography of barium swallow showed œsophageal obstruction at the level of the lower edge of the aortic arch (Dr. T. Harrison). *Hoarseness had now developed.* A Witzel's gastrostomy was done on Jan. 26, but patient died on Feb. 2. Permission for necropsy was refused.

I wish to thank Dr. A. W. Baker and Dr. F. B. Smith for permission to record this case.

R. T. COOKE.

Department of Pathology, Royal Infirmary, Preston.

PSYCHOANALYSIS IN THE NATIONAL HEALTH SERVICE

SIR,—Clause 1 (1) of the National Health Service Bill states: "It shall be the duty of the Minister . . . to promote . . . a comprehensive health service designed to secure improvement in the physical and mental health of the people . . . and the prevention, diagnosis, and treatment of illness . . ." Nevertheless, psychotherapeutic, and especially psychoanalytic, treatment cannot be generally provided since psychiatrists trained in psychotherapeutic methods are only available in numbers sufficient to cope with a minute proportion of the total need. The number of patients being treated by psychoanalysis is indeed small compared to the need, but the number is not insignificant. Psychoanalysis is relatively new, it is time-consuming, and it is costly. Its use in treatment and in research cannot now be successfully controverted. The situation after the passage of the new Bill will be that a branch of the profession will be able to cope with the psychoanalytic treatment of a few hundred patients at one time, and the therapy is one which is known to exist to many. Any Minister of Health would be embarrassed at having to make regulations designating priorities for treatment, and if the selection is left to the individual practitioner there is sure to be heartburning in his medical colleagues who refer him patients. If psychoanalysis is not accepted as a treatment to be provided under the Bill there will be justified resentment among patients who are advised such treatment. If psychoanalysis is accepted in any degree the vast needs for training will become apparent.

At present the official body organises training in psychoanalysis and psychoanalytic treatment under the auspices of a clinic at small fees or free, and arranges publication and library facilities. The present endowment and fees are such that slow development is likely to continue to be possible without State aid. Under the new Bill eventual organisation as a part, for example, of the British Postgraduate Medical Federation, might become possible. Under clause 16 (1) the Minister is able to aid research, and perhaps eventually psychoanalytic research might obtain State subsidy. Nevertheless, it seems to be inevitable, though unfortunate, that psychoanalytic therapy, training, and research will for a time run an independent course.

London S.W.7. W. CLIFFORD M. SCOTT.

DEATH AFTER CURARE

SIR,—With reference to your annotation of Sept. 21, too much discredit is being thrown on a drug which was not entirely responsible for this fatality. With a woman aged 70 years, surely a dose of 'Pentothal' of the magnitude of 1 gramme was more than sufficient on its own for the performance of an appendicectomy lasting 43 minutes; yet to this a dose of 'Intocostrin' of 9 c.cm. (equivalent to 27 mg. of *d*-tubocurarine chloride) was added.

Since pentothal and curare are synergic in action, seems strange that with these large doses no referenc was made to the necessity for controlled or assiste respiration during the operation; reliance seems to hav been placed more on 'Coramine' and 'Veritol' tha artificial ventilation of the lungs with oxygen whe *cyanosis was first noted.* Surely the cause of death wa prolonged *hypoxia,* with *toxæmia* as a secondary cause

May I add a rider that in all cases of gross respiratory depression an unobstructed airway must be ensured and controlled respiration performed before resort is made t respiratory stimulants.

London, S.W.1. E. ASQUITH.

SIR,—Your report on this case raises many issues c great importance. At a time when anæsthetists ar attempting to establish curare as a safe and useful dru it is very tragic that such a case should occur. Yet man useful lessons may be learnt from it. Apart from you report the case is unknown to me, and I assume that th facts as reported are correct.

(1) The wisdom of using a new and experimenta drug (I am aware some may question the epithet) o such a bad risk case appears to me doubtful in th extreme. It would be very useful if the opinions of m senior colleagues on this could be ventilated in yo columns. I use the term "experimental" deliberatel for there is a drug still used by some of us, known ether, which has been employed as an anæsthetic age for 100 years on many millions of cases. Any new dr which has been in use for only a few years on a fe thousand cases must, by comparison, be termed "exper mental."

This appears to me to be an important principle establish. In an evening paper recently an anæsthetist reported to have stated that in a certain fatal case cura was used as being the safest possible drug in the circu stances. Compared with ether, it is very doubtful curare could at present be correctly described as th safest possible drug in any circumstances. Before th value of any anæsthetic drug can be assessed it mu be used in hundreds of thousands of cases over a lo period. Some drugs have such obvious limitations th their value, or lack of it, is soon discovered. Othe of greater promise, require a longer trial. For examp yclopropane, which appeared at the outset to have such reat promise, required five years of trial before it could e said to have passed the experimental stage. Curare, which appears to be of even greater value than cyclopropane, will probably require an even longer trial. I hope that, unlike 'Pentothal,' it will not prove to be a drug "fatally easy" to administer.

---

[1] Leading article, *Lancet*, 1945, ii, 406.

(2) When we examine the dosage of drugs used in his case, it would appear that the coroner's verdict was charitable. An old lady of 70, suffering for two days from an acute abdominal infection, and with early peritonitis, was given morphine gr. $^{1}/_{4}$ and atropine gr. $^{1}/_{100}$. I would presume to say that the former drug was superfluous. This was followed by 1 g. of pentothal. In my opinion this was an excessive dose, even had nitrous oxide been the only additional anæsthetic to be given. With curare in a fit subject in first-class condition I personally hesitate to give more than half this dosage. Prescott, Organe, and Rowbotham (*Lancet*, July 20, p. 80) have pointed out the danger of giving two such respiratory depressants together in full dosage. The present case illustrates this danger. I am not surprised that the patient required continuous oxygen.

This was followed by 'Intocostrin' 9 c.cm.—180 units. Presumably this was given intravenously in a single dose. So far as I am aware, 100 units of this drug is regarded by authorities as a maximum single dose even in fit subjects. In any case, we are warned that in the very young, or the very old, or in bad risk cases, this dose must be considerably reduced. I hope that those who are more competent than myself to express an opinion will let us know in your columns whether this dosage should be regarded as excessive.

I have the deepest sympathy with the anæsthetist in this case, of whose identity I am ignorant. "There, but for the grace of God, go I." But I should like to obtain the opinions of my colleagues on the following four principles:

(1) New anæsthetic drugs must be assessed in comparison with ether.
(2) Final assessment cannot be made until many hundreds of thousands of administrations have been recorded. During this period of trial such drugs should be regarded as experimental.
(3) Such experimental drugs should not be given to bad risk cases.
(4) The dosage of such experimental drugs should be carefully regulated according to the published recommendations of senior anæsthetists.

It is only with the object of establishing these principles that, with humility and hesitation, I have sought the hospitality of your columns at such length.

London, W.1. R. BLAIR GOULD.

SIGMOIDOSCOPY IN AMŒBIC DYSENTERY

SIR,—I should like to add a postscript to my article of Oct. 13, 1945 (p. 460). Two points call for revision in the light of subsequent experience.

The first of these concerns technique. I have since found that the most satisfactory method of producing a "clean" lower bowel, whether for the diagnostic purpose of a sigmoidoscopy or for the therapeutic purpose of a retention enema, is by the simple administration of a weak bicarbonate enema, after which a period of 4–6 hours must be allowed to elapse. At the end of this period, regardless of the taking of meals meanwhile, the lower eight inches of bowel are almost invariably clean and "dry," in the sense that all traces of enema fluid have been evacuated or absorbed. An important point, and one often overlooked, is that the evacuant enema must be of just that volume which will produce an effective call to stool: this will be one pint in some, considerably more or less in others. There are still undesirable methods in use involving the exhibition of castor oil, &c., and I have known retention enemata given within a few minutes of the evacuant enema, thereby reducing the strength of the medicament used to quite ineffectual proportions. Such errors in technique not only defeat their object but often involve a sore trial for the long-suffering patient.

Secondly, a point in diagnosis. Recently I have seen a number of cases in which the ulcers are minute: with the ordinary magnifying lens they catch the eye merely as tiny points of extreme congestion. They are scattered in small groups, and frequently only one such group can be found. With a special magnifying attachment, first shown me by Lieut.-Colonel A. M. Khan, R.A.M.C., it is possible to detect the actual tissue loss.

Keighley, Yorks. C. F. J. CROPPER.

NON-SPECIFIC EPIDIDYMITIS

SIR,—Dr. Whitwell's letter of Sept. 7, recalling Slesinger's suggestion that non-specific epididymitis may be due to stress reflux of normal urine, prompts me to describe an experiment carried out at my suggestion by Dr. G. L. Timms, pathologist to Kenya Government Medical Service.

A rabbit was anæsthetised and 5 c.cm. of urine withdrawn by vesical puncture. Of this, a part was cultured and proved sterile. Of the remainder, 0·5 c.cm. was injected into the previously exposed vas deferens on one side. As this was done the epididymis could be felt to inflate with urine. The animal remained clinically normal after this operation; after 10 days the testis and epididymis on both sides were removed and sectioned. They were all normal.

As Handley says (*Lancet*, 1940, i, 779), the reflux theory does not seem very feasible; and this experiment appears to show that normal urine is not an irritant in the epididymis, at least in the rabbit.

London, W.1. F. RAY BETTLEY.

TUBERCULOUS GLANDS AND CALCIFEROL

SIR,—With reference to the treatment of tuberculous glands with high dosage of calciferol (July 20, p. 88), there seems to be some evidence that such treatment, while helpful when sinus formation is present, has a clinically adverse effect on glands which have not broken down. In the absence of more detailed investigation this is little more than an impression, but it would be in keeping with the observation that in the early stages of treatment of lupus vulgaris with calciferol there is not infrequently a local exacerbation of the disease. It would also be in keeping with similar observations on the influence of tuberculin in tuberculous lesions and of arsenic in untreated syphilis. Until further evidence is forthcoming it would appear advisable to use the calciferol treatment with caution when lung tuberculosis is present, since such a reaction in the lung might have disastrous sequels.

London, W.1. H. J. WALLACE.

NEW WORDS ABOUT OLD AGE

SIR,—In your issue of August 10 (p. 211) Dr. Howell discusses "the nomenclature of old age." It would be a benefit to medicine if you would help to get the "new words" fixed in correct form before it is too late.

From *pais* (stem *paid-*) a child, we have "pædiatrics," and from *geron* (stem *geront-*), an old person, we should have "gerontiatrics," *not* "geriatrics." There is no word *geria* in Greek, though there is *eugeria*, meaning a good old age. Gerontiatrics therefore is the word for the medical care of the aged and eugeria is its goal.

Orpington, Kent. H. ST. H. VERTUE.

TECHNIQUE OF PREFRONTAL LEUCOTOMY

SIR,—In order to avoid incision of the grey matter, I *suggest that* prefrontal leucotomy might be performed through an approach from the midline underneath the angular gyrus by an incision of the corpus callosum in the direction of its fibres. No doubt a special knife would have to be designed and a new technique devised for the new approach.

Taunton. T. F. G. MAYER.

*** We are informed that section from this angle would carry an appreciable risk of damage to the optic nerves.—ED. L.

THE Medical Research Council have received from Sir Leonard Rogers, F.R.S., a further addition to the endowment for research in tropical medicine with which he entrusted them in 1920. The capital value of this fund is now about £15,000, and the income is applicable to special purposes within the general field of tropical medical research.

PERNICIOUS ANÆMIA AND CARCINOMA OF THE ŒSOPHAGUS

SIR,—Nineteen years after the death sentence in pernicious anæmia (P.A.) was commuted to "liver for life" it is now becoming generally recognised that the patient with P.A. is more liable to gastric carcinoma than is his healthy neighbour.[1] The best examples of this concurrence seen here in the past few years were (1) a man with P.A. diagnosed by blood-count, barium meal, test-meal, &c., in July, 1938, who died, aged 37, in September, 1943, three months after laparotomy had revealed inoperable gastric carcinoma; and (2) a woman, first admitted to hospital with P.A. in October, 1933, who died in September, 1942, at the age of 39, after a short history of gastric upset; her neoplasm was proved by necropsy and histology. These two patients were considerably younger than in most of the recorded cases.

I have not been able to find any record of œsophageal cancer in a patient with P.A., and the following presumptive case is reported in the hope that others may look out for such cases.

A man, aged 49, was first sent to this department on March 31, 1938, by Dr. H. T. Cank, of Leyland, for a blood-count. He had had pneumonia in 1932 and 1933, and several attacks of "influenza" since, the last being a few weeks ago and attended by pain suggesting pleurisy. He had long been easily tired, had lost weight, and had recently noted soreness of the tip of his tongue.

His brother was known to the department as a case of P.A., having attended regularly since August 1, 1935, when he was 32 years old. Otherwise the family history was clear of anæmia and cancer.

Apart from clinical anæmia, physical examination was *negative. Blood-count showed red cells 2,500,000 per c.mm.*, Hb 70% (Haldane), C.I. 1·4; white cells 7200 per c.mm. (differential count normal). The mean red-cell diameter was 8·2 μ (halometer).

After treatment with 'Campolon' the blood became normal by April 27, 1938. On a dose of 2 c.cm. every three or four weeks, blood-counts were normal in March and July, 1939. Patient was seen once in 1940, thrice in 1941, and the figures were normal in four counts in 1942 and three counts in 1943, when 'Anahæmin' was being given. A test-meal in November, 1941, showed a histamine-fast achlorhydria. In January, 1943, patient was in hospital for four weeks with a left lobar pneumonia. He left hospital 17 lb. heavier than on admission.

On Jan. 5, 1944, he was readmitted, complaining that for three months he had been regurgitating food about an hour after eating, and that for six weeks he had felt food stick at about the level of the mid-length of the sternum. Despite a good appetite he had lost much weight, and he had sternal pain radiating to the right axilla.

He was wasted, and the right pupil was larger than the left. Blood-count was normal. Radiography of barium swallow showed œsophageal obstruction at the level of the lower edge of the aortic arch (Dr. T. Harrison). Hoarseness had now developed. A Witzel's gastrostomy was done on Jan. 26, but patient died on Feb. 2. Permission for necropsy was refused.

I wish to thank Dr. A. W. Baker and Dr. F. B. Smith for permission to record this case.

R. T. COOKE.

Department of Pathology, Royal Infirmary, Preston.

PSYCHOANALYSIS IN THE NATIONAL HEALTH SERVICE

SIR,—Clause 1 (1) of the National Health Service Bill states: "It shall be the duty of the Minister . . . to promote . . . a comprehensive health service designed to secure improvement in the physical and mental health of the people . . . and the prevention, diagnosis, and treatment of illness . . ." Nevertheless, psychotherapeutic, and especially psychoanalytic, treatment cannot be generally provided since psychiatrists trained in psychotherapeutic methods are only available in numbers sufficient to cope with a minute proportion of the total need. The number of patients being treated by psychoanalysis is indeed small compared to the need, but the number is not insignificant. Psychoanalysis is relatively new, it is time-consuming, and it is costly. Its use in treatment and in research cannot now be successfully controverted. The situation after the passage of the new Bill will be that a branch of the profession will be able to cope with the psychoanalytic treatment of a few hundred patients at one time, and the therapy is one which is known to exist to many. Any Minister of Health would be embarrassed at having to make regulations designating priorities for treatment, and if the selection is left to the individual practitioner there is sure to be heartburning in his medical colleagues who refer him patients. If psychoanalysis is not accepted as a treatment to be provided under the Bill there will be justified resentment among patients who are advised such treatment. If psychoanalysis is accepted in any degree the vast needs for training will become apparent.

At present the official body organises training in psychoanalysis and psychoanalytic treatment under the auspices of a clinic at small fees or free, and arranges publication and library facilities. The present endowment and fees are such that slow development is likely to continue to be possible without State aid. Under the new Bill eventual organisation as a part, for example, of the British Postgraduate Medical Federation, might become possible. Under clause 16 (1) the Minister is able to aid research, and perhaps eventually psychoanalytic research might obtain State subsidy. Nevertheless, it seems to be inevitable, though unfortunate, that psychoanalytic therapy, training, and research will for a time run an independent course.

London S.W.7. W. CLIFFORD M. SCOTT.

DEATH AFTER CURARE

SIR,—With reference to your annotation of Sept. 21, too much discredit is being thrown on a drug which was not entirely responsible for this fatality. With a woman aged 70 years, surely a dose of 'Pentothal' of the magnitude of 1 gramme was more than sufficient on its own for the performance of an appendicectomy lasting 43 minutes; yet to this a dose of 'Intocostrin' of 9 c.cm. (equivalent to 27 mg. of *d*-tubocurarine chloride) was added.

Since pentothal and curare are synergic in action, it seems strange that with these large doses no reference was made to the necessity for controlled or assisted respiration during the operation; reliance seems to have been placed more on 'Coramine' and 'Veritol' than artificial ventilation of the lungs with oxygen when cyanosis was first noted. Surely the cause of death was prolonged hypoxia, with toxæmia as a secondary cause.

May I add a rider that in all cases of gross respiratory depression an unobstructed airway must be ensured and controlled respiration performed before resort is made to respiratory stimulants.

E. ASQUITH.

London, S.W.1.

SIR,—Your report on this case raises many issues of great importance. At a time when anæsthetists are attempting to establish curare as a safe and useful drug it is very tragic that such a case should occur. Yet many useful lessons may be learnt from it. Apart from your report the case is unknown to me, and I assume that the facts as reported are correct.

(1) The wisdom of using a new and experimental drug (I am aware some may question the epithet) on such a bad risk case appears to me doubtful in the extreme. It would be very useful if the opinions of my senior colleagues on this could be ventilated in your columns. I use the term "experimental" deliberately, for there is a drug still used by some of us, known as ether, which has been employed as an anæsthetic agent for 100 years on many millions of cases. Any new drug which has been in use for only a few years on a few thousand cases must, by comparison, be termed "experimental."

This appears to me to be an important principle to establish. In an evening paper recently an anæsthetist is reported to have stated that in a certain fatal case curare was used as being the safest possible drug in the circumstances. Compared with ether, it is very doubtful if curare could at present be correctly described as the safest possible drug in any circumstances. Before the value of any anæsthetic drug can be assessed it must be used in hundreds of thousands of cases over a long period. Some drugs have such obvious limitations that their value, or lack of it, is soon discovered. Others, of greater promise, require a longer trial. For example, lopropane, which appeared at the outset to have such at promise, required five years of trial before it could said to have passed the experimental stage. Curare, ich appears to be of even greater value than cyclo- opane, will probably require an even longer trial. I pe that, unlike 'Pentothal,' it will not prove to be drug "fatally easy" to administer.

---

[1] Leading article, *Lancet*, 1945, ii, 406.

(2) When we examine the dosage of drugs used in is case, it would appear that the coroner's verdict was aritable. An old lady of 70, *suffering for two days* om an acute abdominal infection, and with early eritonitis, was given morphine gr. $^1/_4$ and atropine . $^1/_{100}$. I would presume to say that the former drug as superfluous. This was followed by 1 g. of pentothal. n my opinion this was an excessive dose, even had itrous oxide been the only additional anæsthetic to be iven. With curare in a fit subject in first-class condition personally hesitate to give more than half this dosage. Prescott, Organe, and Rowbotham (*Lancet*, July 20, . 80) have pointed out the danger of giving two such espiratory depressants together in full dosage. The present case illustrates this danger. I am not surprised hat the patient required continuous oxygen.

This was followed by 'Intocostrin' 9 c.cm.—180 units. Presumably this was given intravenously in a single dose. So far as I am aware, 100 units of this drug is regarded by authorities as a maximum single dose even in fit subjects. In *any* case, we are warned that in the very young, or the very old, or in bad risk cases, this dose must be considerably reduced. I hope that those who are more competent than myself to express an opinion will let us know in your columns whether this dosage should be regarded as excessive.

I have the deepest sympathy with the anæsthetist in this case, of whose identity I am ignorant. "There, but for the grace of God, go I." But I should like to obtain the opinions of my colleagues on the following four principles:

(1) New anæsthetic drugs must be assessed in comparison with ether.

(2) *Final assessment cannot be made until many hundreds* of thousands of administrations have been recorded. During this period of trial such drugs should be regarded as experimental.

(3) *Such experimental drugs should not be given to bad risk cases.*

(4) The dosage of such experimental drugs should be carefully regulated according to the published recommendations of senior anæsthetists.

It is only with the object of establishing these principles that, with humility and hesitation, I have sought the hospitality of your columns at such length.

THE Medical Research Council have received from Sir Leonard Rogers, F.R.S., a further addition to the endowment for research in tropical medicine with which he entrusted them in 1926. The capital value of this fund is now about £15,000, and the income is applicable to special purposes within the general field of tropical medical research.

Obituary

CHARLES FERRIER BEEVOR

M.A., B.M. OXFD

Mr. C. F. Beevor, surgeon to the ear and throat department of the Royal Waterloo and Evelina Hospitals, died on Sept. 15 at the age of 62. A son of Dr. C. E. Beevor, the well-known neurologist, he was educated at Charterhouse, and Magdalen College, Oxford, where he graduated in 1906, taking honours in chemistry in the final school of natural science. Continuing his medical training at University College Hospital, he took his B.M. in 1912, soon afterwards becoming house-physician to Sir John Rose Bradford, and later a house-surgeon at Charing Cross Hospital.

Early in his career he became interested in otolaryngology, and worked in the special department at U.C.H. until 1915, when he went to Egypt with a commission in the R.A.M.C. as an otological specialist at one of the clearing stations, where he remained until he was invalided home in 1918. Not long after this he took up his work again as a specialist and was appointed to the staffs of the Royal Waterloo Hospital and the Evelina Hospital. His successful practice included many friends and colleagues.

"Essentially an individualist," writes M. D., "Charles Beevor hated regimentation and resented interference by red tape with his own individual methods of work. It was, perhaps, largely this peculiarity which militated against his chances of promotion in the academic world of medicine, but his comparative freedom from such commitments gave him more scope to develop his gifts in his own way. His individualism inevitably resulted in faults which sometimes showed themselves to his disadvantage: but in his professional practice it expressed itself as a great kindliness and in a disposition to spare no trouble where his patient's comfort was concerned, and his friends loved him for his loyalty no less than for his good fellowship."

Mr. Beevor leaves a widow and two daughters.

HAROLD FRANCIS LEWIS HUGO

M.C., M.B. LOND.

Dr. H. F. L. Hugo, who died at Crediton on Sept. 14 at the age of 60, had an unusually promising career as a student which suggested that he might have made a considerable reputation had he wished to do so. He elected, however, to become a general practitioner, and for more than thirty years practised at Crediton, to its great comfort and benefit. His work was interrupted by the first world war, when he served with distinction as medical officer to the Devon Yeomanry, by whom he was greatly and rightly beloved. His kindness, firmness, and courage did much to sustain the unit through bad times in Gallipoli and elsewhere.

Like so many good men he was profoundly dissatisfied with himself though infinitely forgiving to others. His patience was inexhaustible, his humour abundant, sometimes betraying his lively Gallic ancestry. As a young man he was a "class" soccer player, and he remained a useful fastish bowler till well on in the thirties. He was, moreover, a good bridge player, though perhaps he got—and gave—as much fun out of golf, which he was wise enough not to take seriously, and billiards or snooker, in which he fluked outrageously. His keen interest in natural history developed with the years. The loss of both his sons in the recent war was a blow from which he never recovered though he did not murmur and continued to work as long as he could.

Many will mourn the passing of a handsome, blue-eyed, shy but friendly, and extremely competent doctor who always refused to make speeches but whose wise guidance was invaluable to the many committees to which he was almost automatically elected. L. N. J.

THE death is announced of Sir JOHN HARRIS, M.D., member of the Legislative Council of Victoria since 1920 and minister of public instruction and public health for the State from 1935 to 1941. He graduated M.B. at the University of Melbourne in 1890 and practised in his native town of Rutherglen, in Victoria, till 1917, when he served as medical officer to no. 1 Squadron, Australian Flying Corps, in Palestine. He was appointed K.B.E. in 1937.

Appointments

CHALMERS, J. A., M.D. Edin., F.R.C.S.E., M.R.C.O.G.: gynæcologist and obstetrician in the North of Scotland and hon. charge gynæcologist, Royal Northern Infirmary, Inverness.

CLEGG, J. W., M.R.C.S., D.C.P.: pathologist, Hospital for Consumption and Diseases of the Chest, Brompton.

DAY, F. M., M.R.C.S., D.P.H., D.T.M.: M.O.H., Hammersmith.

DORE, J. C., M.B.N.U.I., D.M.R.: junior asst. radiologist (diagnostic), Middlesex Hospital, London.

FOWLER, ERIC, B.M. Oxfd: examining factory surgeon, Crowborough, Sussex.

FOX, P. P., M.B. Lpool, D.P.H.: M.O.H. for Chard, Crewkerne, and Langport and asst. county M.O., Somerset.

GRIERSON, A. M. M., M.D. Edin.: deputy M.O.H., Manchester.

HAY, A. B., M.B. Aberd., M.R.C.O.G.: gynæcologist and obstetrician in the North of Scotland and hon. charge gynæcologist, Royal Northern Infirmary, Inverness.

MITCHISON, D. A., M.B. Camb.: asst. to the pathologist, Hospital for Consumption and Diseases of the Chest, Brompton.

MOREL, M. P., M.A. Camb., F.R.C.S.: surgeon, North Devon Infirmary, Barnstaple.

St. Bartholomew's Hospital, E.C.1:

HARPER, R. A. K., M.B. Edin., D.R.: director of X-ray diagnostic dept. (whole-time).

LOUGHBOROUGH, G. T., M.R.C.S., D.M.R.E.: M.O., X-ray diagnostic dept. (part-time).

SIMON, GEORGE, M.D. Camb., D.M.R.E.: M.O., X-ray diagnostic dept. (part-time).

London Chest Hospital, E.2:

BARLOW, DONALD, M.S. Lond., F.R.C.S.: asst. surgeon.

BROWN, A. I. P., M.B. Lond., D.A.: anæsthetist.

LINDAHL, J. W. S., M.CHIR. Camb., F.R.C.S.: asst. laryngologist.

MOUNTFORD, L. O., M.B. Camb., D.A.: anæsthetist.

ROSE, ALICE C., M.B. N.Z., M.R.C.P., D.A.: anæsthetist.

Addenbrooke's Hospital, Cambridge:

BERRIDGE, F. R., M.B. Camb., D.M.R.: radiologist.

LLOYD, OSWALD, M.D. Lond., F.R.C.S., M.R.C.O.G.: surgeon to gynæcological and obstetrical depts.

MARTIN, LAURENCE, M.D. Camb., M.R.C.P.: physician.

TRUSCOTT, B. M., M.B.E., M.B. Lond., F.R.C.S.: surgeon.

WRIGHT, G. F., M.B. Camb., D.O.M.S.: ophthalmic surgeon.

Royal Liverpool United Hospital (Liverpool Royal Infirmary):

BAMBER, G. W., M.D. Camb., F.R.C.P.: dermatologist.

MACPHEE, G. G., M.D. Glasg., L.D.S.: dental surgeon.

SEATON, D. R., M.B. Camb., M.R.C.P., D.T.M. & H.: asst. physician for tropical diseases.

WHITAKER, P. H., M.D. Lpool, D.M.R.E.: radiologist.

Colonial Medical Service:

ANTONIO, R. F., M.B. Edin.: M.O., Gold Coast.

ASHE, GEOFFREY, M.B. Manc.: M.O., British Somaliland.

BALEAN, G. T., M.R.C.S.: M.O., Zanzibar.

BEST, A. M., M.R.C.S.: M.O., Uganda.

COOPER, P. R., B.M. Oxfd, D.T.M.: M.O., Nigeria.

HANDFORTH, J. R., M.B. Camb.: M.O., Hong-Kong.

MACDONALD, Captain W. H., M.B. Lond.: M.O. (grade II), Western Pacific.

PABLOT, P. J., M.B. Lond., D.T.M. & H.: M.O. (grade I), Mauritius.

SMITH, Lieut.-Colonel G. G., M.R.C.S.: M.O., British Honduras.

STONES, P. B., M.B. Lond.: M.O., Nigeria.

WATERSTON, WILLIAM, L.R.C.P., L.D.S.: M.O., Kenya.

WEST, J. H., M.R.C.S.: anæsthetist, Uganda.

The appointments to the Bradford Royal Infirmary announced in our issue of Sept. 14 were made under the auspices of the Bradford Joint Hospitals Council and are not to the infirmary alone but to all the hospitals in the city.

Births, Marriages, and Deaths

BIRTHS

ASHFORD-BROWN.—On Sept. 14, in London, the wife of Dr. W. H. Ashford-Brown—a son.

HEANLEY.—On Sept. 18, in London, the wife of Mr. Charles Heanley, F.R.C.S.—a son.

MILLS.—On Sept. 17, in Birmingham, Dr. Margaret Mills, D.A., wife of Mr. W. G. Mills, F.R.C.S.—a daughter.

OLIVER.—On August 29, at Sheffield, the wife of Dr. G. B. Oliver—a son.

RUDLAND.—On Sept. 20, at Coventry, the wife of Surgeon Commander R. S. Rudland, R.N.V.R.—a daughter.

MARRIAGES

LIGHT—BELL.—On Sept. 14, in London, Lovell Hillier Ben[illegible] Light, M.R.C.S., to Colyeen Audrey Bell.

LONGLEY—DRURY.—On August 22, at Felpham, John Douglas Brougham Longley, M.R.C.S., to Elizabeth Clara Dru Drury.

DEATHS

BOYCOTT.—On Sept. 17, at St. Albans, Arthur Norman Boycott, M.D. Lond., aged 80.

COOK.—On Sept. 19, John Howard Cook, M.S. Lond., F.R.C.S., formerly of C.M.S. medical department, aged 75.

COOPER.—On Sept. 13, in Maine, U.S.A., Harold Merriman Cooper, O.B.E., M.B. Lond., formerly of Hampton-on-Thames, Middlesex, aged 74.

GILBERT.—On Sept. 12, at Naini Tal, India, Leonard Erskine Gilbert, C.I.E., M.D. Lond., lieut.-colonel I.M.S., retd., aged 7[illegible].

HOLMES.—On Sept. 15, at Godalming, Richard Annesley Holmes, M.R.C.S., aged 61.

HUGO.—On Sept. 14, at Crediton, Devon, Harold Francis Lewis Hugo, M.C., M.B. Lond., aged 60.

WATTS EDEN.—On Sept. 22, Thomas Watts Eden, M.D. Edin., F.R.C.P., F.R.C.O.G., aged 83.

Notes and News

WESTMINSTER HOSPITAL AND THE INFANTS HOSPITAL

THE governing bodies of Westminster Hospital and the Infants Hospital, Vincent Square, have agreed to the merging of their two institutions. The Infants Hospital, which has been used during the war as a hospital for officers of the United States Forces, will be reopened as soon as possible ; the "Westminster Children's Hospital." A good deal of r-raid damage will have to be repaired before its services n be fully developed, but the bed accommodation will entually be increased to 140.

The fusion of the two hospitals will make it possible to ncentrate all pædiatric services and research at Vincent quare, where Westminster Hospital students will have xceptional opportunities for the study of children's ailments.

This is one of several affiliations being negotiated by estminster Hospital following the recommendation made the report of the Ministry of Health survey. The hospital as also recently taken over two convalescent homes with 60 beds situated in the country a short distance from London r the reception of patients in an early state of convalescence here after-treatment and industrial rehabilitation can be onducted.

JOURNALS AND BOOKS WANTED ABROAD

Dr. A. Tudor Hart tells us that the International Brigade ssociation has had urgent requests from former medical officers f the I.B. Medical Service in the Spanish War, now working nce more in their own countries, for current issues of medical ournals. "Would some of your subscribers," he asks, "be villing to forward their *Lancet* regularly for a year? If so, vill they please write to the secretary, International Brigade Association, 14, Red Lion Square, London, W.C.1, who will let them have a name and address. We have other former olleagues still working in China to whom we should especially like to forward recent and expensive surgical textbooks. May we also appeal for some donations for this object? They should be sent to the same address marked 'Medical Textbook Fund.'"

DENTISTS' FEES UNDER N.H.I.

THE British Dental Association has approved the decision of the General Advisory Dental Council to advise dentists to refuse all dental benefit letters but to treat patients privately at the scale of fees rejected by the Ministry of National Insurance. The representatives of the association will not take part in the work of the Dental Benefit Council until the dispute is settled.

HOSPITALS AND HEALTH CENTRES IN U.S.A.

THE President of the United States has signed the Hospital Survey and Construction Act, authorising Federal expenditure of 375 million dollars during the next five years for the construction of hospitals and health centres, and 3 million dollars for the surveys which must precede such construction. Each State is to develop its own programme for hospitals and health centres, to be administered by State authorities under standards specified by the U.S. Public Health Service. Any State may initiate action by submitting a request to the surgeon-general of this service for funds to carry out an inventory of existing hospitals, and to prepare a plan for the construction necessary to provide adequate care for all the people. In defraying the survey expenses Federal funds must be matched by two to one. Allotments for actual construction will not be made until the State plan based on the survey findings has been approved. Construction allotments to individual States will vary in amount: States with a lower per-capita income, where there is relatively greater need for medical facilities, will receive larger allotments per head. Before any individual project is approved by the surgeon-general, it must be shown that two-thirds of the total cost of construction is available from other-than-Federal sources, and that money can be found to maintain and operate the institution after completion.

In the view of Dr. Thomas Parran, the surgeon-general, "this Act sets for the first time a national policy which makes it clear that hospitals in the future must be planned, located, and operated in relation to the overall health needs of the people. . . . Adequate hospitals, health centres, and related physical facilities are the essential workshops, without which it is not possible to provide even a minimum of modern health and medical services."

R.N. SICK BERTH STAFF

SINCE 1933 the Central Council of the Royal Naval Sick Berth Staff Associations have been helping the men of the Royal Naval Sick Berth Staff to find posts as male nurses on their return to civil life, and through their efforts attendants with suitable qualifications are now registered as Service-trained male nurses.

There are now vacancies on the council, and R.N. or R.N.V.R. medical officers, active or retired, who would be willing to help in this work are asked to write to Surgeon-Captain M. H. Knapp, c/o Medical Department, Admiralty, 64, St. James's Street, London, S.W.1.

SCABIES FILM REVISED

THE M.O.I. film *Scabies* has been revised and is to be reissued early in November by the Central Office of Information under the title *Scabies 1946*. The latter half dealing with treatment has been largely retaken, new shots being inserted, and the commentary has been entirely rewritten.

Starting as before with good close-ups of the habits and development of the mite, the film shows next the characteristic sites of infestation; after this is inserted new material showing the range of drugs available for treatment and their relative efficiency, and then the film goes on as before to show the method of applying benzyl benzoate emulsion. The sequence on the relative merits of treating secondary infection or the infestation first has again been glossed over, but more emphasis is now laid on the importance of treating the whole family rather than the individual.

This new version, which has been shortened to run for 24 min., is an improvement on the old even though some avoidable errors have been retained—for instance, the misleading term "microphotography" where "photomicrography" is intended. It will be screened again with benefit even to those who saw the original version.

FOOD RATIONS FOR THE GERMANS

IT was announced in Berlin last Monday that the basic food ration in the British and American zones of Germany will be raised again to 1550 calories daily for the normal consumer from Oct. 14. The decision to increase the ration at once, although there is no certainty of maintaining supplies till next harvest, has been taken because of the urgency of the situation as depicted in the June report of the tripartite committee of investigation (*Lancet*, 1946, i, 896: July 6, p. 22). This report said that for ordinary consumers the ration of 1550 calories achieved last winter, when supplemented with unrationed foods, barely sufficed to maintain health.

BLOOD-TRANSFUSIONS IN SCOTLAND

IN the quarter ended June 30, 1946, hospitals in Scotland used 4136 pints of whole blood for transfusion, compared with 4094 pints in the previous quarter, and their demands for liquid plasma rose from 830 to 1448 pints. The Scottish National Blood Transfusion Association was able to meet the increased need, 7888 pints of blood being obtained from donors in the June quarter, a rise of 657 pints over the March total.

HOME PRODUCTION OF STREPTOMYCIN

FOUR British firms are to coöperate with the Ministry of Supply, the Ministry of Health, and the Medical Research Council in the pilot-scale production of streptomycin, and it is hoped that preliminary clinical trials will begin before the end of 1946. The firms concerned are Messrs. Boots, Glaxo Laboratories, and the Distillers Company, who are all established penicillin manufacturers, and the Heyden Chemical Company, who are to instal a factory to make penicillin and streptomycin at Ardrossan, Scotland.

Streptomycin will not be released for general medical use until the conditions which respond to it have been clearly established, and the clinical trials will take a considerable time. Meanwhile plans will proceed for large-scale production to meet the demands of the medical profession as a whole. The drug is already undergoing clinical trials in the United States in all types of tuberculosis, dysentery, typhoid, and paratyphoid fever, and certain infections of the urinary tract, particularly those which do not respond to penicillin or sulphonamides. Supplies in America are at present too small for any substantial quantity to be made available for this country.

It seems likely that streptomycin will be more expensive than penicillin on a per-case basis.

Major T. M. PEMBERTON, F.R.C.S., R.A.M.C., has been appointed M.B.E. in recognition of gallant and distinguished service while a prisoner-of-war.

University of Leeds

The inaugural lecture of the faculty of medicine will be given at 3.30 P.M. on Monday, Oct. 14, when Lieut.-General Sir William MacArthur, F.R.C.P., will speak on Insect-borne Disease and English History.

Society of Apothecaries of London

Diplomas in industrial health have been granted to the following: A. Anderson, K. Biden-Steele, M. P. Fitzsimons, G. B. Oliver, G. F. Keatinge. This list replaces that published on Sept. 7 (p. 368).

Welsh National School of Medicine

The opening address for the new session of this school is to be given by Sir Wilson Jameson, chief medical officer of the Ministry of Health, in the Institute of Physiology, Newport Road, Cardiff, on Friday, Oct. 4.

Faculty of Homœopathy

Dr. C. E. Wheeler will deliver his presidential address to the faculty at the London Homœopathic Hospital, Great Ormond Street, London, W.C.1, on Thursday, Oct. 3, at 5 P.M. His subject is to be Looking Before and After.

Royal Medical Society

On Friday, Oct. 11, at 8 P.M., at 7, Melbourne Place, Edinburgh, Sir Henry Wade will give the inaugural address of the 210th session of this society. He is to speak on the Life of an Edinburgh Medical Student 300 Years Ago.

Irish Tuberculosis Society

At a meeting of the society to be held at Newcastle Sanatorium, co. Wicklow, on Saturday, Oct. 19, at 2 P.M., Dr. F. R. G. Heaf will read a paper on Recent Trends in Tuberculosis, Dr. Dorothy Price will discuss whether B.C.G. vaccination is a practical proposition in Ireland, and Prof. F. J. Henry will speak on Surgery in the Treatment of Tuberculosis.

St. Thomas's Hospital

The old students' dinner will take place at Claridge's Hotel, Brook Street, London, W.1, on Nov. 1, at 7.30 P.M. Sir Maurice Cassidy is to take the chair. The number of places is limited to 250, and applications should be sent to the secretaries of the dinner committee, St. Thomas's Hospital, S.E.1.

Royal Sanitary Institute

On Wednesday, Oct. 9, at 2.30 P.M., at 90, Buckingham Palace Road, London, S.W.1, Dr. W. R. Martine, senior assistant M.O.H. for Birmingham, and Mr. R. S. Cross, chief sanitary inspector for Brighton, will open a discussion on the Public Health Aspects of the Manufacture of Ice-cream.

"Anæsthesia"

The first number of this quarterly journal, which Dr. C. Langton Hewer is editing on behalf of the Association of Anæsthetists of Great Britain and Ireland, will appear on Oct. 1. The publishers are George Pulman & Sons, Ltd., Thayer Street, London, W.1.

An Italian Medical Students' Association

An Associazione Studentesca Internazionale has been founded in the University of Padua and has taken the name of the Digamma-Pi Association from Sinclair Lewis's *Doctor Arrowsmith*. It seeks to promote friendship and exchange of information and opinions between medical students all over the world, and would welcome inquiries addressed to it (in any European language or Esperanto) at the Liviano Palace, University of Padua, Italy.

Middlesex Hospital and the New Service

Mr. T. Money-Coutts, treasurer of the Middlesex Hospital, speaking at a meeting of the court of governors reported in the *Times* of Sept. 19, said he looked forward to the future of the hospital under the new National Health Service with confidence and enthusiasm. It had been said that the new Act would change the character of the voluntary hospitals, but he believed that 200-year-old traditions such as theirs had the strength not only to survive but to thrive on changes inherent in the development of our social system. The character of an institution depended not on Acts of Parliament but on the personality and ideals of those who worked for it. For those who had helped the voluntary hospitals in the past the new Act was not a signal for abdication but a challenge, and the Middlesex would continue to depend on the interest of their friends to maintain and improve their standards for treating the sick.

He added that the medical school was flourishing, and that women students will be admitted for the first time in October.

National Hospital, Queen Square

On Monday, Sept. 30, at 4 P.M., Dr. Gordon Holmes, F.R.S., will give the inaugural address of the first post-war course of clinical neurology to be held at this hospital.

Return to Practice

The Central Medical War Committee announces that Dr. W. Lindesay Neustatter has resumed civilian practice at 128, Harley Street, W.1 (Welbeck 3686).

Divine Healing and General Medical Practice

Dr. H. E. Collier will give the first of three monthly lectures on this subject at Denison House, 296, Vauxhall Bridge Road, London, S.W.1, on Wednesday, Oct. 16, at 7 P.M. The lectures are being given under the auspices of the Churches Council of Healing founded by the late Archbishop Temple.

International Hæmatological Conference

The International Hematology and Rh Conference will be held in Dallas, Texas, on Nov. 15. The guest speakers will include: Dr. Philip Levine (Linden, New Jersey), Dr. R. R. Race (London), Dr. William Dameshek (Boston), Dr. Ernest Witebsky (Buffalo), Dr. I. Davidsohn (Chicago), Dr. Louis K. Diamond (Boston), Dr. Ludwig Hirszfeld (Wroclaw, Poland), Dr. Ignacio Gonzalez Guzman and Dr. E. Uribe Guerola (Mexico City), and Dr. J. M. Hill (Dallas). The secretary of the conference is Dr. Sol Haberman, Baylor University Hospital, Dallas, Texas.

Messrs. Ward, Blenkinsop & Co. have moved from Liverpool and their address is now 6, Henrietta Place, London, W.1 (Langham 3185).

A CORRESPONDENT points out that in our annotation of Sept. 7 (p. 352) on hybrid corn, the word *diœcious* was used when *monœcious* was intended.

PENICILLIN IN BILE.—In our annotation on penicillin and sulphathiazole in typhoid fever (Sept. 7, p. 353) the remark that penicillin is concentrated in the bile should read: "Penicillin is excreted in the bile in concentrations similar to, or even higher than, those attained in the blood" (see Rammelkamf, C. H., Helm, J. D. *Proc. Soc. exp. Biol., N.Y.* 1943, 54, 31).

Medical Diary

SEPT. 29 TO OCT. 5

Tuesday, 1st

ROYAL COLLEGE OF SURGEONS, Lincoln's Inn Fields, W.C.2
3.45 P.M. Prof. H. A. Harris: Clinical Anatomy of the Lymphatic System.
5 P.M. Prof. Geoffrey Hadfield: The Reticuloses.
ROYAL SOCIETY OF MEDICINE, 1, Wimpole Street, W.1
8.30 P.M. *Orthopædics.* Mr. V. H. Ellis: Injuries of the Cervical Spine. (Presidential address.)
LONDON SCHOOL OF DERMATOLOGY, 5, Lisle Street, W.C.2
5 P.M. Dr. J. E. M. Wigley: Eczema.

Wednesday, 2nd

ROYAL COLLEGE OF SURGEONS
3.45 P.M. Prof. H. A. Harris: Growth of Bones.
5 P.M. Dr. Montague Maizels: Liver Efficiency Tests.
ROYAL SOCIETY OF MEDICINE
2.30 P.M. *History of Medicine.* Sir Arthur MacNalty: Evolution of English Preventive Medicine. (Presidential address.)
UNIVERSITY OF GLASGOW
8 P.M. (Department of Ophthalmology.) Mr. John Foster: *An Ophthalmic Tour of Switzerland.*

Thursday, 3rd

ROYAL COLLEGE OF SURGEONS
3.45 P.M. Prof. H. A. Harris: Epiphysial Growth Cartila
5 P.M. Dr. Montague Maizels: Liver Efficiency Tests.
ROYAL SOCIETY OF MEDICINE
8 P.M. *Neurology.* Dr. Douglas McAlpine: Disseminated Sclerosis. (Presidential address.)
LONDON SCHOOL OF DERMATOLOGY
5 P.M. Dr. G. Bamber: Misuse of Antiseptics and other Medicaments in Dermatology.
EDINBURGH POSTGRADUATE LECTURE
4.30 P.M. (Royal Infirmary.) Mr. J. R. Cameron: Congenita Abnormalities of the Kidney.

Friday, 4th

ROYAL COLLEGE OF SURGEONS
3.45 P.M. Prof. F. Wood Jones, F.R.S.: Anatomy of the Skin.
5 P.M. Prof. J. Z. Young, F.R.S.: *Nerve Injury* and Nerv Regeneration.

Saturday, 5th

INTERNATIONAL SOCIETY OF MEDICAL HYDROLOGY
9 A.M. (Buxton.) Dr. J. Van Breemen: Four Causal Factors o Rheumatic Disease.
5.30 P.M. Mr. R. Whittington: *Plasma Viscosity.*

CONDUCING TO THE CURE

SOCIAL PSYCHIATRY IN THE TREATMENT OF NEUROSYPHILIS BY INDUCED MALARIA

MAEVE WHELEN
M.D. Lond., D.P.M.
MEDICAL OFFICER I C MALARIA THERAPY CENTRE, HORTON EMERGENCY HOSPITAL

M. H. BREE
PSYCHIATRIC SOCIAL WORKER

> "Life is short and Art is long; the Crisis is fleeting: Experiment risky; Decision difficult. Not only must the physician be ready to do his duty, but the patient, the attendants and external circumstances must conduce to the cure."

THIS famous aphorism of Hippocrates expresses a profound truth. Medicine originated as a social art. Hospitals are the descendants of purely social agencies, the hospices of the early Christian era which gave shelter not only to the sick but to the poor, the aged, orphans, and travellers: later their functions were separated and the hospital caring only for the sick appeared. Sickness was regarded as a social phenomenon, as possession by the devil, as punishment for wrongdoing, and so on. This gradually gave way to the scientific approach to disease and the sick person became an interesting pathological specimen rather than an individual member of the community. We are now entering the era of the synthesis of these two outlooks on sickness, and it is more and more widely recognised that a patient is not only a carrier of a disease process but is also an individual, a person living in a community who reacts upon and is reacted upon by that community. Sir Arthur MacNalty (1943) expressed this well when he said that one of the first steps in public-health reform was the realisation that all forces—medical, environmental, social, and individual—must be used to maintain national health and combat disease.

The work of Canby Robinson at the Johns Hopkins Hospital (Robinson 1939) is further evidence of the need for the collaboration of medicine and social science. He studied some hundreds of patients from the emotional and social aspects and found that two-thirds of them had adverse social conditions relating to their illness, and in over half of these the adverse social conditions were giving rise to emotional disturbances. He concluded that the study of the patient as a whole and as a person was essential to good medical practice, and that a knowledge of a patient's difficulties would often throw light on problems in public health and preventive medicine.

This paper is based upon a personal experience of an attempt to link clinical medicine with practical social science. The range of our experience is necessarily limited by the nature of our work, but we feel there are sufficient aspects of it to show the value of this collaboration.

PRACTICAL APPLICATION

The starting-point of our work is the treatment of neurosyphilis by induced malaria. We do not intend to say anything about the strictly medical side of the treatment—this has been done often and well—but to confine ourselves to what might be called its social aspect.

Before going any further we must say a few words about the types of patients admitted for treatment. Since 1940 our range of patients has included a small proportion of certified general paralytics and taboparetics on leave of absence from their mental hospital for the purposes of treatment; a much larger proportion of relatively early cases who do not require certification to bring them under treatment; tabetics; cases of syphilitic optic atrophy with or without other clinical signs; asymptomatic cases without any clinical signs or symptoms but with cerebrospinal fluid (C.S.F.) positive on routine testing. Most of our patients have acquired syphilis, but some have congenital syphilis and vary from the gross mental defective to the asymptomatic case.

Illness, especially if it is prolonged and serious, always engenders a situation fraught with anxiety, which involves not only the sick person himself but also his family and sometimes his friends. This anxiety, although each case will have its specific factors, is based fundamentally on fear of the illness itself and what it may betoken—actual or potential economic stress and uncertainty about the future. Fear of the illness itself may be aggravated if there is a feeling that there is something mysterious about it and that it is not properly understood. A large proportion of our patients are admitted with $1^1/_2$–2 years' history of vague but progressive symptoms; in some cases there have been repeated visits to the doctor and various hospitals, only to be told there is nothing wrong or to be given a week or two's sick-leave as a placebo. Finally they become so ill that they have to be admitted to hospital, and a thorough investigation reveals the cause of all the trouble. Throughout this time there has been a gradually increasing anxiety, which is often very greatly eased as soon as a definite course of action is proposed.

Emotional reaction to the illness is absent in the grossly psychotic or demented, but it is worth while to remember that it may be present in a patient showing mental symptoms. One of the worst cases of this sort of anxiety we have seen was in a man with mild confusion and severely impaired memory who was aware of his disabilities and knew the nature of his illness. He was a most pathetic object, and, owing to his mental condition, very difficult to help.

Sickness invariably raises economic problems for the patient and his family, and unless these can be quickly and satisfactorily settled they may give rise to a great deal of unnecessary distress. This situation should be dealt with as expeditiously and sympathetically as possible by the medicosocial worker.

Lastly there is the question of the future. This involves not only the outcome of the actual illness but, in many cases, the patient's ultimate re-establishment in the community. It is often very difficult or impossible to give a definite answer. The best one can do is to give a simple and straightforward explanation, bearing in mind the differing degrees of intelligence and understanding of those concerned. This has the added advantage of enlisting their coöperation in the follow-up scheme. In this connexion the question of employment is very important. It is probably true that any job is better than no job, so long as it is within the patient's capacity—i.e., neither too hard nor too easy. In general, the best type of work for a discharged patient is that to which he is accustomed, since the resumption of habitual activities helps to compensate to some extent for a slight degree of deterioration. Unemployment leads to boredom, but has the much more serious effect of making the individual feel unwanted and that he has no niche in society. The discussion of future plans with the patient or his family is often very valuable and much appreciated; and if possible it is better to postpone discharge until suitable arrangements have been made. In many cases, of course, the patient has a job to go back to; but where this is not so, it is sometimes possible to help him to get suitable work or training.

Mental symptoms, if present, may be the cause of a great deal of distress to the patient's relatives. The commonest reaction is, "He isn't mental, is he?" We are quite sure the right way to handle this situation is to explain simply but firmly that the patient is for the time being mentally unbalanced, stressing the irresponsibility for his actions. It is often a help to try to show the kinship between physical and mental illness. There is a widespread belief among the lay public that mental illness is incurable, and that admission to a mental hospital means incarceration for life. It is often difficult to convince people otherwise, but an attempt should be made. If admission to a mental hospital becomes necessary, permission is more easily given and anxiety allayed if it is pointed out that today mental hospitals are primarily hospitals and not places of detention, and that it is possible to ask for and obtain a patient's discharge. If a patient shows much mental instability, it is imperative to make an effort to keep him in hospital until this has cleared up; occasionally it is impossible to do this, and he has to be allowed to discharge himself against advice, with the risk that he may prejudice his future prospects by his unbalanced behaviour, even though the prognosis of ultimate recovery is excellent. If a patient is being discharged with some degree of mental deterioration, it is as well to explain his limitations carefully to a responsible relative and to give some idea as to how to handle him.

What has been said so far, except for the section on mental symptoms, is applicable to most types of serious illness, but in neurosyphilis there is the additional factor of the syphilis with its moral implications. There seems to be a very understandable disinclination among doctors to tell patients or their responsible relatives the nature of the illness. We feel that whenever possible the patient should be told what is the matter; and, in view of the risk of infection of other members of the family and the consequent need of routine testing, it is helpful if the patient can be persuaded to tell his or her marital partner or allow the doctor to do so. In cases where the patient is too ill, mentally or physically, to give consent we usually tell the spouse on our own responsibility. This does not mean that every patient or relative concerned should be told everything; in dealing with a disease like syphilis it is absolutely essential to treat each case individually and to use the utmost discretion. It is important to realise that ignorance about venereal disease may be great, and the implications of tabes, or general paralysis, or even syphilis may be unappreciated. This can lead to difficulties if information is unwittingly broadcast to relatives, friends, or neighbours. We have met this catastrophe more than once.

The knowledge that the disease is venereal, even where there was previous suspicion, gives rise to considerable emotional disturbance in both the patient and his family, with which one must be prepared to deal. The most pressing need is usually an opportunity to "get it off their chests"; this entails giving them a chance to talk about the illness, to ask questions and so on, apart from the time spent on taking a history. There may be great anxiety lest other members of the family are infected or may learn the nature of the illness. It is essential to urge the necessity of doing blood tests and, if necessary, lumbar punctures on all relatives who have run the risk of infection. This in itself may help to allay one type of anxiety. An early reassurance that neurosyphilis is not contagious removes a load of often unexpressed worry. We have known cases where trained nurses have aroused this groundless fear by isolating the patient or taking precautions to protect themselves after learning the diagnosis. In other cases the only thing that can be done is to reassure about professional secrecy, but it must be borne in mind that, although it is possible to guarantee that no member of the staff will give any information, the same cannot be said for other patients and their relatives. We have had several cases where either the patient or his family has learnt the nature of the illness in this way.

The initial shock once over, the atmosphere is often a good deal clearer, and one gets increased coöperation in the treatment, a vital factor in a disease where treatment is long and tedious. Some time ago we had a certified general paralytic whose wife had been an inpatient with syphilitic ulceration of her legs. On discharge she was advised to attend as an outpatient for further treatment. She did so regularly until the blitz made travelling difficult, when she lapsed. She was seen in connexion with her husband's illness and told what was the matter. Her immediate response was "Why ever wasn't I told this before? Of course, if I had only known it was so serious I should never have left off going for treatment, however difficult it was to get there." If there is any contra-indication to explaining the exact nature of the illness, a partial explanation may prove useful, although this is not accepted at its face value so easily since the Ministry of Health started its campaign against venereal disease. People are now rather apt to jump to the right conclusion!

A point that needs mentioning is the attitude of the staff to V.D. Anyone who feels that it is a moral rather than a medicosocial question should not work in the department. The staff must be able to accept the patient as a patient. This attitude of acceptance can be most helpful, especially in cases where there is considerable emotional reaction to the V.D. A patient of ours was admitted in a great state of emotional upheaval because of this. He was bitterly ashamed of his illness, terrified that his family would get to know what was wrong, and certain that anyone who knew what was the matter would regard him as an outcast. The change in his whole demeanour when he found that he was not looked upon as a pariah but was accepted as a member of the ward community was striking. He was converted from a potentially very difficult patient into one who was coöperative and helpful, and a possible full-blown neurotic breakdown was averted.

The situation engendered by the illness with its anxiety and stress may give rise to a superadded neurosis in the patient or a potential or actual neurotic breakdown in the family. The latter not only produces another sick person but will react adversely on the original patient and still further complicate the family situation.

It is a direct benefit to the community for a sick person to be restored to the best degree of health possible, and every facility should be given for the reabsorption into employment of all the partially disabled, whether physically or mentally handicapped, who are capable of doing useful work. With this end in view it is essential that the liaison between the hospitals and the employment exchanges should be strengthened and expanded. Many adverse social conditions—e.g., the cost of treatment just at the time when the income is lowered, bad housing, congestion, lack of recreational facilities—need to be radically altered for the whole community. Efforts are made to help patients individually, but it must be recognised that, unless these reforms are carried out, any special priority given to one means, under present conditions, that he receives it at the expense of another, who may in his turn suffer through the deprivation.

ILLUSTRATIVE CASES

CASE 1.—Male, married, aged 32, was admitted in April, 1943. For the past three years he had been "making the rounds of the hospitals," feeling something was wrong with him but getting no satisfaction. About six months before admission he began to lose confidence in himself and became afraid he would have an accident and injure his passengers (he was a tram-driver). He found it difficult to convince anyone that he was ill and unfit to drive, though he was eventually transferred to point work, but by then he felt unfit to work at all. Finally his behaviour became so disordered that he was admitted to an observation ward and then transferred to us.

On admission he was at times euphoric and mildly grandiose and at others appreciated what was wrong and was anxious to be treated. He was infected with malaria and had twelve peaks of fever of 103° F or over. Immediately after treat-ient his mental symptoms became more pronounced, and e was interfering, truculent, and emotionally unstable. his abated pretty quickly and, although still rather uncertain, e responded to a simple explanation about his illness and reatment and agreed to go as a voluntary patient to a mental ospital. The desirability of attending the follow-up clinic fter his discharge was also explained to him.

He stayed in the mental hospital from July, 1943, to February, 1944. He was seen by us in November, 1943, at the request of the mental hospital. He then appeared, in view of his negligible degree of dementia and enhanced stability, rather too well adjusted to hospital life; so we recommended that an attempt should be made to find him suitable work or training through the rehabilitation department. He was therefore sent to an aftercare home in February, 1944, and arrangements were being made to place him, when he walked out leaving no address.

In April, 1944, he wrote saying it was nearly six months since his last lumbar puncture, and he thought he was due for another; so could he have an appointment? He turned up on the appointed day showing a remarkable improvement. He said that on leaving the aftercare home he had spent a couple of days putting his affairs in order and had then got a job helping on a crane. When last seen in September, 1946, he had maintained his improvement and was still holding down the same job.

This patient's coöperation was enlisted by giving him a simple individual explanation at a time when he was able to appreciate that this was done in his own interests, and that the situation demanded the coöperation that we believed he could give.

CASE 2.—Male, married, aged 62, was admitted in December, 1942. He was fairly well educated, and had his own small business. He had had lightning pains for about twelve years and had undergone a gradual change in personality during the last five or six years, becoming progressively duller, mildly suspicious, and careless about his bills. From February, 1942, he began to have frequent lapses of memory, lost his business acumen, and made serious mistakes in his estimates. His wife eventually became afraid of his driving a car or handling financial matters and insisted on his seeing a specialist.

On admission he was slow, dull, disorientated, and mildly grandiose. He was infected with malaria, having 13 peaks of fever of 103° F or over. After treatment his mental symptoms suddenly increased; he became acutely hallucinated, confused, and restless. His wife's consent was obtained for his transfer to an observation ward; but action was deferred, as he began to show signs of improvement and then rather suddenly became simple, childish, and well-behaved.

His wife, who knew the nature of the illness and whose blood was negative, was faced with the problem of his business; if he was going to recover, then she wanted to keep it if possible; if he was not going to be fit to direct it again, then she wanted to dispose of it. The position was explained to her as clearly as possible, and it was pointed out that it was impossible to give a definite prognosis. She decided to try to keep the business going for the time being.

When he finally settled down, his wife thought she could look after him at home. Fortunately he was amenable to suggestion and agreed not to touch any business affairs for at least six months but to rest and take things quietly.

Four months later, when he attended the follow-up clinic, he showed a slight improvement. His wife reported that he could make a satisfactory estimate, although he later confused the jobs. He did not attempt to interfere in any way, apparently as a part of his rest treatment.

He was seen again in April, 1944, when his wife reported a steady improvement in business capacity and said they had made a profit of £550 as against a steady loss while he was in hospital. He still, however, showed signs of slight residual deterioration—e.g., a slightly impaired memory and a mild emotional instability. He was last seen in April, 1946, and had maintained his improvement.

This case illustrates the patient's rehabilitation through his family and the importance of suitable employment. The ultimately comparatively successful outcome was due not only to the treatment but also to the able coöperation of his wife, which was enlisted by giving her a good understanding of the situation.

CASE 3.—Female, married, aged 45, a high-grade mental defective, admitted December, 1942. On admission she was emotionally unstable and slightly amnesic. She was infected with malaria and had 12 peaks of fever of 103° F or over. After treatment she became acutely psychotic, declared she was Gracie Fields and broadcast every evening, and was very confused and uncertain. This cleared up fairly quickly, and when she was discharged she was childish and mildly deteriorated but not very noticeably below her original poor level.

Her husband was a thin anxious individual with a fair degree of intelligence. He had been brought up in an institution and then gone into the Navy. He married soon after his discharge, mainly to have a home. He had not known his wife long and soon regretted the marriage. They had two children (now aged 24 and 23) very soon after marriage. About this time he contracted syphilis, had about two years' treatment, and was told he was cured. Unfortunately he infected his wife: she had some treatment and then lapsed. As a result of all this he had a markedly ambivalent attitude towards his wife, expressing remorse for his "crime," resentment at his "bad luck," and anger with his wife for not having continued her treatment, with the result that he had worried for years over the possible later effects on her. Lately he had felt numb on rising and had pain in the back of his head. He and his daughters had tests which gave negative results.

He was given a full and simple explanation about his wife's treatment and prognosis and had special interviews when visiting her and later when he brought her to the follow-up clinic. He became better able to deal with his remorse, resentment, and lack of affection for his wife. While his wife was acutely psychotic he was asked to give his consent to her certification. This produced an intense conflict, as intellectually he could see the benefit to his wife, his daughters, and himself; but his lack of affection and the realisation of the difficulties he would have to shoulder if she came home seemed to offer a method of self-punishment or expiation.

After his wife's discharge he gradually settled down. He clearly appreciated her innate limitations and shouldered all the major responsibilities in the home, but without the self-accusatory and self-punishing colouring which were so much to the fore at first, and the physical symptoms of which he complained while his wife was in hospital have disappeared.

This case illustrates the need to deal with an emotional disturbance in a member of the patient's family. If the obligation to the husband had been limited to testing his blood and cerebrospinal fluid, it is possible that his mental conflict would have resulted in a neurotic breakdown, which would have adversely affected his daughters and his working capacity and would have made the patient's chance of adjustment outside an institution very unlikely.

DISCUSSION

Medicine for a long time has concerned itself mainly with the curing of disease, but now its scope has been enlarged to include the maintenance of health. This entails the consideration of the patient as an individual and not simply as a carrier of disease; Mr. A must be Mr. A and not just a "case of hæmorrhoids." All factors that are adversely affecting him must be considered with a view to their elimination or mitigation, either by enabling him to deal with them himself or by actually removing or altering them by outside interference. In future, not only must the physician be ready to use all the medical knowledge and resources available to him but he will accept, as part of his duty, the obligation to assist "the patient, the attendants and external circumstances" to "conduce to the cure."

"Prevention is better than cure" is a popular and true slogan. It will be more often achieved if all opportunities are utilised. For instance, if a close friend or relation has been exposed to infection or to an emotional situation with which he cannot cope, an attempt should be made to arrest the trouble before it has had time to develop. Case 3 is an example where this was done successfully.

The increasing complexity of medicine means that the doctor can no longer work satisfactorily in isolation but must be a member (albeit the responsible member) of a team containing medical and non-medical personnel. It is impossible for the doctor, even if he has the time, to deal with all the social aspects of an illness, as he has not the necessary training and knowledge. This side of the illness is far better dealt with by a trained medico-social worker, working in the closest collaboration with the doctor.

Team-work and enlarging the scope of clinical medicine will open up a great field of research, embracing mental hygiene, prophylaxis, and social medicine.

CONCLUSIONS

The emphasis should be shifted from the curing of an illness to the wider conception of the promotion of optimum health. This entails the recognition of each patient as *unique;* a particular individual, in a particular family, in a particular environment.

The wider outlook means that the patient's family is included in the total picture, with the result that incipient trouble in another member of the family is more likely to be noticed and dealt with prophylactically before it further aggravates the situation.

The criterion of successful treatment is the degree of satisfactory functioning of the patient in society. This entails coöperation between medicine and social science.

We wish to thank Dr. W. D. Nicol, medical superintendent of Horton Emergency Hospital, for his interest and coöperation.

THE USE OF REASSURANCE

T. G. ARMSTRONG
M.D. Camb., M.R.C.P.

LATE LIEUT.-COLONEL R.A.M.C.; OFFICER I/C MEDICAL DIVISION OF A GENERAL HOSPITAL

It is to be regretted that during the last fifty years of scientific progress the management and handling of patients has been neglected in the medical curriculum. The personal, and often intimate, methods of the older physicians are being replaced by highly specialised or materialistic impersonal methods.

The management of patients, though not an exact science, is, or should be, part of a discipline comprising method and technique. It can be studied and improved in the same way as other scientific disciplines. Training in this subject is necessarily more difficult than the simple acquisition of facts. Much depends on the establishment of sympathetic contact with patients, and perhaps yet more on experience. Our only training has been in the hard school of experience over many years. Much time could have been saved and long periods of sickness avoided if the principles of personal therapeutics had been taught in our medical schools.

Six years of military medicine have provided a valuable lesson in the handling of young active patients whose main desire is to get well, as opposed to older folk who often "enjoy ill health" and in whom it can even be a disservice to cure their imagined ailments. Neurosis is just as common in the Services as it is among civilians; but, owing to this desire to get well, it is much more easily treated. I intend here to show how this can be done by reassuring the patient.

VALUE OF REASSURANCE

Reassurance (by which I mean the allaying of the patient's anxiety) is of great value not only in treating neurosis but also in cases of organic disease. Fear of an existing organic disease often produces greater disability than does the disease itself. Silence, except the gravest maladies or with patients of the lowest intelligence, is inconsiderate and even dangerous. T few patients are told the cause of their complaint; t little is said of the probable duration of treatme and the ultimate outcome. I have been impressed b the value to the happiness of my patients of a fra explanation of their disease and its prognosis. I hav also been depressed by the frequency with which patient who have been previously investigated have received no indication of the nature of their malady. Curiously, this neglect has been most noticeable when the findings have been negative.

After making a diagnosis, whether of organic disea or neurosis, some doctors overtreat patients by useless methods. Lengthy treatment for incurable disabilitie is a potent cause of additional ill health. The oft repeated bottle of medicine, the continued application of physiotherapy, and the weekly certificate are poo substitutes for sympathetic explanation and encouragement to keep at work and make the best of not to bad a job. With young people simple explanation reassurance, and minor psychotherapy have been s often effective in forestalling serious invalidism an curing existing disabilities that I have thought it wort while to describe here the simple method used. It mus be emphasised that simplicity is the keynote. Th approach has always been that of the general physician and no attempt has been made to treat major psycho neurotic illnesses; nor have psycho-analytic method at any time been used.

METHOD OF REASSURANCE

The Doctor's Diagnosis.—No patient can have fu confidence in his doctor if a complete examination ha not been carried out, and no doctor can confidentl reassure his patient without having carried out such a examination. Organic disease should only be diagnose when there is reasonable proof that it is present. It i better to attribute incorrectly a small percentage of organi illnesses to functional causes than to condemn a larg number of healthy patients to the fear of a non-existen disease. If a functional disturbance is diagnosed, th doctor should appreciate his good fortune rather tha decide (as he too commonly does) that this is yet anothe piece of medical junk to be thrown on the scrap-heap o disinterest.

The Patient's Diagnosis.—What does the patient consider his malady to be? What organ does he think i diseased? What is his attitude to his condition? Wha does he fear? Does he fear a progressive illness leadin to total incapacity? The answers to these questions ar of the greatest value. Without them no real reassuranc can be given to a patient with functional disease, fo unknown fears cannot be calmed. These questions ar as important as a full physical examination; they mus be viewed "in daylight," recognised, and frankly discussed. Occasionally the patient will spontaneousl voice his fears. More often he must be questioned. I is best to ask a general question such as, "What do yo think is the matter with you?" But it may be necessar to put it in specific terms: to a patient complaining o left inframammary pain on exertion "Do you fear you heart is affected?"

A healthy soldier, aged 23, who had been regraded t category B for effort syndrome following diphtheria, continue to complain of dyspnœa, precordial pain, and palpitatio on the least exertion. Asked his opinion of the cause, h said that he thought he had permanently injured his hear Early in the first siege of Tobruk he had been admitted t hospital with faucial diphtheria and told that he must remai at complete rest in bed, as otherwise his heart might b damaged. Unfortunately, owing to extreme pressure on th orderlies, he had to get up to obtain food and to visit th latrines. He was later evacuated to the base and kept a omplete rest for six weeks; but he believed that irreparable amage had been done during the first week in Tobruk.

After specific reassurance his symptoms disappeared and o his great satisfaction he was regraded to category A1.

Other Doctors' Diagnoses.—It is always worth while in complaints of functional origin, especially those referred to the heart, to ask if any doctor has ever told the patient the nature of his illness. Opinions given by doctors always carry great weight with patients and heavily influence their opinion about themselves. A patient who has been told that he has a "strained heart" or "a little weakness of the heart" will be convinced that he has some form of heart disease. His belief will at least modify his attitude to exercise, and at the most will produce a fear—not readily expressed—of sudden death. Previous positive diagnoses are often reported by patients with heart-consciousness or effort syndrome. If such a diagnosis of organic disease remains fixed in the patient's mind and is not discussed, reassurance by a second doctor is clearly useless. Conviction of the absence of organic disease is an absolute essential for reassurance and recovery; and can only be achieved *if the final opinion is* completely accepted and the original opinion of organic disease rejected. Often the first opinion will be found to have been correct and reasonable, but to have been misinterpreted by the patient; frank discussion, and a statement that the disease which had been present at the time of the previous opinion has cleared meanwhile, will often reassure the patient.

A healthy soldier, aged 23, complained of precordial pain, palpitation, and dyspnœa on exertion. There were no abnormal signs. His regimental medical officer had told him that he had mitral stenosis and should be invalided home. He was reassured but did not get well. On direct questioning, he admitted disagreement with my reassurance; he felt that his own medical officer, who had watched him for a long time, knew his case well. He believed that his medical officer's opinion was correct and mine wrong. He refused to accept my reassurance and retained his symptoms.

Emotional Upset.—It is useful to inquire for emotional upset at or before the onset of illness. Occasionally there has been a severe mental trauma; more often a succession of minor disturbances have exerted a cumulative effect. The following case-record from civil practice is an example of a single mental trauma.

A young man, aged 19, a factory messenger, complained of three months' left inframammary pain, palpitation, and dyspnœa on exertion. These had been so severe that for the last two months his doctor had kept him off duty.

On examination he had no physical signs He was asked if anything notable had happened to him about the time of the onset of his illness. He replied, "No, I don't think so. Nothing much, except that my girl friend broke off her engagement to me." He was asked casually if he was suffering from a broken heart. He burst into emotional laughter lasting several minutes.

The situation was explained to him, and he was assured that he had no organic disease. His pain on exertion ceased abruptly after the interview. He was given a week's graduated exercises to restore his confidence, after which he returned to work, and six months later he was still at work and had no symptoms.

His illness and two months' incapacity for work could have been prevented by prompt reassurance at the onset.

Such cases are unusual; more often a succession of annoyances have impaired morale and rendered the patient conscious of minor disabilities which would not normally trouble him or induce him to report sick.

Explanation.—If organic disease has been excluded, this must be carefully explained to the patient. It is especially necessary at the outset to gain the patient's coöperation and confidence. The doctor must tell him clearly that he does not believe him to be a "lead-swinger" and must explain to him the nature of functional disease. It is useless to try to reassure a patient by telling him that there is nothing wrong with him. He knows that he is ill: his symptoms tell him so. It is equally unprofitable to tell him that he is imagining his complaint; this will injure his self-respect, suggest that he is malingering, and destroy his confidence in the doctor. The doctor must openly admit that the patient's symptoms are genuine, and must explain the reasons for the symptoms. On his ability to satisfy the patient by explanation will depend the success of treatment.

Men who have had a minor organic illness—e.g., fibrositis of the back—may, under the stress of emotional or environmental factors, persist in complaining of pain after all signs of active disease have disappeared; the pain has become a habit. Sometimes such pains are partly fostered by the continued adoption of a faulty posture originally due to attempts to ease a real pain. The explanation of such a case, followed by a short course (not more than fourteen days) of re-educative exercise, will relieve the patient's symptoms without causing him any loss of self-respect. It must be emphasised that there is no longer any organic disease, and that *the treatment prescribed is merely re-educative.* The patient should be led to believe that his symptoms are due to lack of confidence in his body, and that he is simply being taught how to cure himself.

In suitable cases, particularly in functional disturbances of the gastro-intestinal tract and of the cardiovascular system, the mechanism of emotional reaction should be simply explained. The patient should be told how emotion can alter the working of an organ and so cause real discomfort and pain. Examples should be given. It should be pointed out that everyone knows that sudden fear occasioned by a nearby explosion will cause a rise in pulse-rate in normal people. It is common for normal men in the emotional strain of waiting for an examination to experience frequency of micturition. Such examples may be given to illustrate the reaction of emotion. Stomach disorders are more complicated; but, besides mentioning the indigestion that may follow fear and the anorexia that may accompany love, it is useful to explain that direct visual observation of the interior of the stomach has established that its lining membrane becomes congested or inflamed under the influence of severe emotional stress.

In some cases it may be necessary to explain to the patient that a person who believes he has a disease unconsciously focuses his attention on the incriminated organ and becomes, for example, heart-conscious or stomach-conscious. In other words, he becomes unduly sensitive to normal reactions in those organs.

Final Reassurance.—In pure functional disorders it should be stated, emphatically and without any "hedging" or the expression of any doubt, that no organic disease exists. There must be no room in the patient's mind for any doubt about the doctor's opinion. The doctor should also find out if the patient has accepted his opinion. If the patient has not done so, further explanation may be necessary. If, in spite of this, the patient still refuses to accept the doctor's opinion and makes some such remark as "But why do I get this pain?" the prognosis is bad.

OTHER TREATMENT

As a rule, in the absence of organic disease, specific treatments should not be ordered. But in some cases such treatment is useful for saving self-respect, restoring confidence, and maintaining coöperation. In such cases *the adjuvant treatment* should aim at progress and not rest. Rest in bed is recommended too often and for too long; it fosters the belief in a serious disease. It should be made clear to the patient that the treatment is not meant to counteract a disease but to assist his natural resources. To a man with functional backache graduated exercises are important; being out of training he must readjust himself gradually, and if he does too but must be a member (albeit the responsible member) of a team containing medical and non-medical personnel. It is impossible for the doctor, even if he has the time, to deal with all the social aspects of an illness, as he has not the necessary training and knowledge. This side of the illness is far better dealt with by a trained medico-social worker, working in the closest collaboration with the doctor.

Team-work and enlarging the scope of clinical medicine will open up a great field of research, embracing mental hygiene, prophylaxis, and social medicine.

CONCLUSIONS

The emphasis should be shifted from the curing of an illness to the wider conception of the promotion of optimum health. This entails the recognition of each patient as *unique*; a particular individual, in a particular family, in a particular environment.

The wider outlook means that the patient's family is included in the total picture, with the result that incipient trouble in another member of the family is more likely to be noticed and dealt with prophylactically before it further aggravates the situation.

The criterion of successful treatment is the degree of satisfactory functioning of the patient in society. This entails coöperation between medicine and social science.

We wish to thank Dr. W. D. Nicol, medical superintendent of Horton Emergency Hospital, for his interest and coöperation.

It is common for normal men in the emotional strain of waiting for an examination to experience frequency of micturition. Such examples may be given to illustrate the reaction of emotion. Stomach disorders are more complicated; but, besides mentioning the indigestion that may follow fear and the anorexia that may accompany love, it is useful to explain that direct visual observation of the interior of the stomach has established that its lining membrane becomes congested or inflamed under the influence of severe emotional stress.

In some cases it may be necessary to explain to the patient that a person who believes he has a disease unconsciously focuses his attention on the incriminated organ and becomes, for example, heart-conscious or stomach-conscious. In other words, he becomes unduly sensitive to normal reactions in those organs.

Final Reassurance.—In pure functional disorders it should be stated, emphatically and without any "hedging" or the expression of any doubt, that no organic disease exists. There must be no room in the patient's mind for any doubt about the doctor's opinion. The doctor should also find out if the patient has accepted his opinion. If the patient has not done so, further explanation may be necessary. If, in spite of this, the patient still refuses to accept the doctor's opinion and makes some such remark as "But why do I get this pain?" the prognosis is bad.

OTHER TREATMENT

As a rule, in the absence of organic disease, specific treatments should not be ordered. But in some cases such treatment is useful for saving self-respect, restoring confidence, and maintaining coöperation. In such cases the adjuvant treatment should aim at progress and not rest. Rest in bed is recommended too often and for too long; it fosters the belief in a serious disease. It should be made clear to the patient that the treatment is not meant to counteract a disease but to assist his natural resources. To a man with functional backache graduated exercises are important: being out of training he must readjust himself gradually, and if he does too much he will become stiff. Barbiturates are invaluable for inducing sleep in anxious and nervous patients. The *treatment should be short, rarely more than two or three weeks. If no progress has been made at the end of this time it never will be, and continuance of treatment will merely foster belief in its necessity.*

SUMMARY

Reassurance, or the allaying of the patient's anxiety, is of great value not only in neurosis but also in organic disease by removing ill-founded fears.

For reassurance to take effect, the patient must have complete confidence in the doctor, and the doctor complete confidence in his diagnosis. This is best done, in psychogenic cases, by explaining to the patient the mechanism involved.

Adjuvant therapy must be short, to avoid suggesting to the patient that he has a serious disease; and it must be aimed at re-education of the patient.

My thanks are due to Prof. J. A. Ryle for much helpful criticism and advice.

THE POST-HEPATITIS SYNDROME

SHEILA SHERLOCK, M.D. Edin., M.R.C.P.
BEIT MEMORIAL RESEARCH FELLOW

VERYAN WALSHE,* B.Sc. Lond.

From the Department of Medicine, British Postgraduate Medical School, London

Caravati (1944) has described cases of persistent disability following postvaccinial (yellow fever) hepatitis and has designated the condition the "post-hepatitis syndrome."

Benjamin and Hoyt (1945) report a similar series, and during the past two years we have studied a group of soldiers in whom symptoms and usually an enlarged liver have remained after clinical recovery from acute hepatitis. Besides studying the clinical features and making biochemical investigations, we have used the aspiration technique of liver biopsy to study hepatic histology. At the present time, when so many men who have had hepatitis are returning to civilian life, it seems important to report the findings.

Our 20 patients were soldiers of the British, Canadian, and Czechoslovak Armies. All were grade A before contracting acute hepatitis. In 18 the hepatitis was of the simple "infective" type; in 2 it had followed arsenotherapy for syphilis.

The laboratory methods used were the estimation of serum-bilirubin, cholesterol, alkaline phosphatase (King and Armstrong 1934), and total and differential serum proteins. The colloidal-gold reaction (Maclagan 1944), the bromsulphthalein test with a 5 mg./kg. dose and taking 5-min. and 30-min. samples (Helm and Machella 1942), and the intravenous hippuric-acid test (Sherlock 1946a) were also used. Routine urine examination included urobilinogen by Ehrlich's aldehyde reagent, and bilirubin by Hunter's test (Pollock 1945).

Aspiration liver biopsy was performed by the method previously described (Sherlock 1945).

FEATURES OF THE DISORDER

The presenting features were as follows:

	No. of cases		*No. of cases*
Fatigue	18	Fat-tolerance ..	6
Weight-loss	11	Relapse of hepatitis..	8
Anorexia	12	Palpable liver ..	16
Abdominal discomfort	10	Palpable spleen ..	3

Preceding Hepatitis and Relapses.—Of the 20 patients 6 had had more than one acute attack of hepatitis; 1 patient was said to have had six. The last acute episode took place 2–24 months previously.

Symptoms.—The usual complaint was lack of energy and exhaustion on minimal exertion. Inability to regain the weight lost during the acute attack was common. Gastro-intestinal symptoms were prominent; some patients had a poor and variable appetite, with sometimes an aversion to fatty foods. The men were very faddy about their diet. Right upper abdominal discomfort, often aggravated by exertion, was occasionally present.

Consumption of Alcohol.—Of the 20 patients 10 confessed to excessive alcohol intake, 6 took moderate amounts, and 4 were almost teetotal.

Mental State.—A detailed psychiatric examination was not attempted. The British patients were on the whole psychologically ill-balanced. They were extremely introspective and unduly apprehensive about their livers. One was an Army deserter, another had just been invalided from the Services with "effort syndrome." The Canadian group showed better understanding of their symptoms. All, however, had been warded together, and a similarity in the wording of their case-histories was often noticed. Moreover, they were *in hospital* at the end of European hostilities, when there was *delay in* repatriation to Canada, and it was believed that sick men would receive priority.

General Examination.—Despite the complaint of weight-loss, the general development of the group was excellent. Spider angiomata were not seen.

Hepatomegaly.—The most common positive finding was hepatomegaly. The liver edge, smooth and rubbery in consistence, could be felt on inspiration 2–7 cm. below the right costal margin in the nipple line. Tenderness was not present. Liver tenderness on fist percussion over the right lower ribs (Barker et al. 1945) was not elicited.

Splenomegaly.—In 3 patients the spleen could just be palpated under the left costal margin.

Urine Analysis.—This was usually normal, but 5 *patients showed a trace of urobilinogen in an* early morning specimen of urine. Hunter's test for bilirubin was consistently negative.

Biochemical Investigations.—In every patient the serum-bilirubin, the total and differential serum proteins, and the bromsulphthalein test were normal. The serum-cholesterol level was high in 7 cases; in 3 of these it was greater than 300 mg. per 100 ml. Slight changes among the other estimations were a serum-phosphatase of 14 units per 100 ml. in one patient, a weakly positive colloidal-gold reaction in two patients, and in a further two cases the excretion of hippuric acid was at the lower limit of normal (0·7 g. as sodium benzoate). The biochemical observations on the whole, therefore, gave essentially normal results. Caravati (1944) found a low fasting blood-sugar level and flat oral glucose-tolerance curves in some of his patients. Glucose-tolerance tests were performed in 5 of our subjects and gave normal results.

Hepatic Histology.—There was no evidence *of* continuing hepatitis or of cirrhosis. The lobular pattern was not disturbed. The hepatic cells were usually normal and contained their normal complement of glycogen. In 2 instances the glycogen was slightly deficient, and in another there was patchiness of glycogen. Iron was absent both from the Kupffer and the hepatic cells. In one patient who had previously had *malaria*, there was iron in both situations. In ten sections some excess of fat was seen in the liver-cells. It usually took the form of scattered fine droplets evenly distributed through the lobules. In another case the fat was peripheral. Slight fatty change was the only abnormality encountered with any frequency. The Kupffer cells were normal. In 3 patients, all within three months of the initial attack of hepatitis, excess of fibrous tissue was seen in the portal tracts. The picture here resembled *residual* portal scarring following hepatitis (Dible et al. 1943).

ILLUSTRATIVE CASE-RECORDS

CASE 1.—A British officer, aged 31, was fit until October, 1943, when he had infective hepatitis in Libya. He was jaundiced three months and lost two stone in weight. He was invalided home in April, 1944. Since the hepatitis he had had persistent right upper abdominal discomfort, made worse by exercise. Fatty foods caused nausea and flatulence. Appetite was variable. There was exhaustion on walking only half a mile, and some dyspnœa on exertion. In October, 1944, he was again slightly jaundiced and in bed a week. He was a moderate drinker of alcohol.

On examination (March 10, 1945) he was a tall well-developed man, not jaundiced. The smooth rounded liver edge could be palpated 6 cm. below the right costal margin. Tenderness was not present. The spleen was not felt. Urine analysis was normal. The biochemical investigations were normal. Aspiration liver-biopsy sections showed normal liver histology (fig. 1).

This patient was extremely introspective and worried about his health. He had had advice from many doctors, both Army and private, before the present investigation. Even when he was told that his liver was normal the symptoms persisted.

CASE 2.—A Canadian N.C.O., aged 31, had had infective hepatitis at 16 years of age, when he was jaundiced a month. In September, 1944, in Italy, while having arsenotherapy for syphilis, he again became jaundiced for three weeks. The symptoms were those of acute hepatitis.

Since then he had complained of lack of energy and dyspnœa on exertion. The appetite was poor and there was much heartburn and gastric flatulence. During the jaundice the patient lost a stone in weight; this had not been regained. In May, 1945, there was a further attack of hepatitis; jaundice lasted about a week. The symptoms persisted. Cholecystograms were normal. Patient drank a lot of beer, usually six pints a night, with extra beer and spirits at the week-end; this had continued to the date of this investigation (July, 1945).

On examination he looked well. He was not underweight. The liver was palpable 4 cm. below the right costal margin. The spleen was not felt. Urine analysis was normal. The only abnormal biochemical finding was a serum-cholesterol level of 309 mg./100 ml.

Aspiration liver-biopsy sections showed a slight excess of fat within the hepatic cells at the periphery of the lobules; the portal tracts contained a little excess fibrous tissue and showed some round-celled infiltration (fig. 2).

The repeated attacks of jaundice had made both the patient and his medical advisers suspect permanent liver damage. When the present investigation showed this not to be the case he was much relieved and became symptom-free.

DISCUSSION

In the group studied there is no causal relationship between the slight biochemical and the hepatic histological changes and the symptoms. Similar findings have been observed in patients now symptom-free but within six months of clinical recovery from acute hepatitis. In 10 of 15 such subjects the liver was still palpable. Hepatic sections usually showed portal-tract scars, and in 7 excess fat was present in the liver-cells. A raised serum-cholesterol level is also sometimes found during recovery from hepatitis (Sherlock 1946b). Benjamin and Hoyt (1945) believe that the symptoms may have a psychotic basis; the psychoneurotic patterns observed in our patients were very similar to those recorded by these authors. Acute hepatitis is nearly always an unpleasant experience. It usually lasts a minimum of 3–4 weeks. Convalescence is slow. If the illness relapses, as it did in many of this group, fear may arise of further attacks and of permanent liver damage. This is accentuated if a number of men are warded together and repeatedly examined with a view to determining liver size. The condition has not been seen in civilian patients. It is commoner in those serving overseas. Some men feel the disease may provide an opportunity for repatriation. In the type of person affected the condition is somewhat analogous to "effort syndrome," with symptoms focused on the liver and gastro-intestinal tract rather than the heart.

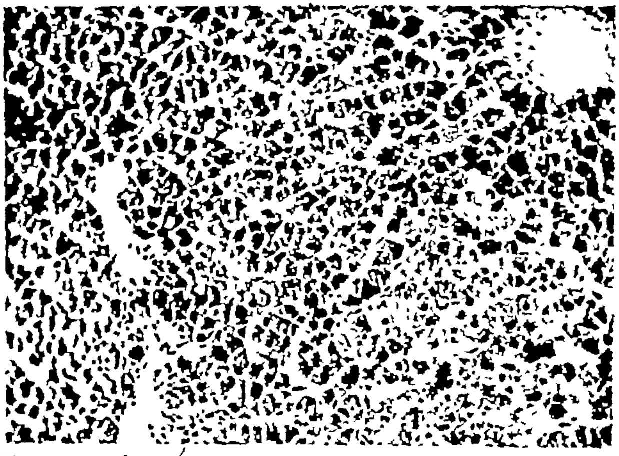

Fig. 1—Normal hepatic structure. Case 1. Best's carmine stain. (× 120.)

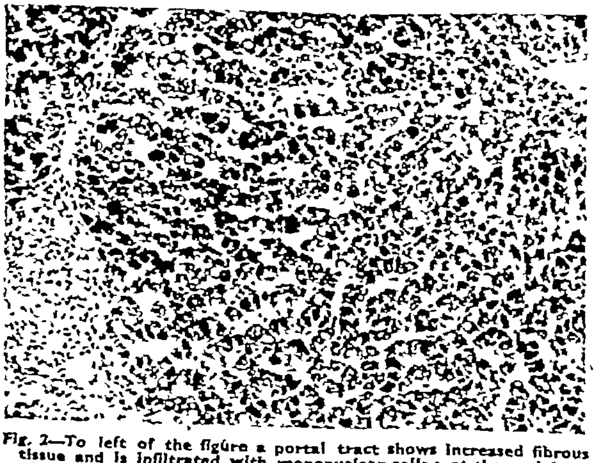

Fig. 2—To left of the figure a portal tract shows increased fibrous tissue and is infiltrated with mononuclear cells; at the periphery of the lobule the hepatic cells show slight fatty change. Case 2. Best's carmine stain. (× 120.)

The hepatomegaly may in some instances be related to the histological picture of fatty change and residual portal-tract scarring. A more likely cause is the downward displacement of a normal-sized liver by the diaphragm. Some patients, with practice, become very efficient at "pushing down the liver." On inspiration the lower liver edge has been observed to move down 6 cm. in one of these patients; an impalpable liver is thus easily felt. Similar considerations apply to the spleen. Moreover, a palpable liver, usually but not constantly due to downward displacement, is not uncommon in normal subjects. On ten occasions such a liver has been subjected to aspiration biopsy with entirely normal results.

The importance of the syndrome is in its distinction from the serious organic sequelæ known rarely to occur after hepatitis (Krarup and Roholm 1941, Dible et al. 1943, Rennie 1945). We have studied 6 patients in whom cirrhosis could be related to a preceding acute hepatitis: 1 showed hepatomegaly, splenomegaly, and abnormal results for all the biochemical methods used; 2 were symptom-free and presented only hepatomegaly; the remaining 3 had clinical features and biochemical findings identical with the series now reported. Clinical and laboratory findings cannot constantly distinguish organic from possibly psychogenic sequelæ; but a definite conclusion can usually be reached after study of aspiration liver-biopsy sections. The importance of this method is emphasised. All the patients volunteered for this procedure and usually derived great benefit from the reassurance possible when results were known.

This sequel of hepatitis may be prevented if patients with the same condition are not herded together. Patients apparently recovering normally should not be examined too often. The condition is unlikely to occur with any frequency in civilians. Treatment consists in reassurance after the fullest possible investigation.

SUMMARY

In 20 patients fatigue and gastro-intestinal symptoms arose, usually with hepatomegaly, after acute hepatitis.

Serum-bilirubin, phosphatase, and differential protein estimations, the colloidal-gold reaction, the intravenous hippuric-acid test, and the bromsulphthalein test showed no abnormalities. There was an occasional rise in serum-cholesterol level.

Hepatic sections obtained by aspiration biopsy were usually normal. In some sections slight fatty change in the liver-cells and occasional scarring in the portal tracts could be seen.

No difference was found between these results and those obtained in subjects who had recovered from acute hepatitis and were now symptom-free.

The possible psychogenic basis of the symptoms is discussed.

The palpable liver seems due to downward displacement of the liver edge rather than to enlargement.

The value of aspiration liver biopsy in the diagnosis of this syndrome from post-hepatitis cirrhosis is emphasised.

We are indebted to Major-General A. G. Biggam, and Lieut.-Colonels W. R. M. Drew and W. H. Hargreaves, of the R.A.M.C., and Brigadier Palmer and Major B. N. Fahni, of the R.C.A.M.C., for many of the cases studied; to Mr. E. V. Willmott for the photomicrographs; and to Mr. D. Bull for the histological preparations.

PATHOLOGY OF POSTANAL PILONIDAL SINUS

ITS BEARING ON TREATMENT

DAVID H. PATEY
M.S. Lond., F.R.C.S.
SURGEON, THE MIDDLESEX HOSPITAL, LONDON

R. W. SCARFF
M.B. Lond.
PROFESSOR OF MORBID ANATOMY AND HISTOLOGY IN THE UNIVERSITY OF LONDON

From the Wards and the Bland-Sutton Institute of Pathology, The Middlesex Hospital, London

PILONIDAL sinus, or postanal dermoid, is found chiefly in young adults, especially in the Services, where unhygienic conditions may be important contributory factors (Davies and Starr 1945).

The length of treatment often necessary for cure becomes a special worry when there is a shortage of man-power, and in many papers, particularly in America, the most striking note is dissatisfaction with the uncertain results of treatment (*British Medical Journal* 1944, Peterson and Ames 1944, Sher 1944, Kooistra 1942). Theis and Rusher (1944) even advise against operation for pilonidal sinus on Service personnel wherever possible.

Dissatisfaction with the position is also reflected in the variety of surgical procedures advocated—e.g., the different methods of demonstrating the tracks and excising them when demonstrated, leaving the wounds open to granulate and epithelise secondarily (Goodsall and Miles 1900, Gabriel 1945); the different methods of primary suture; and various forms of flap closure, such as the Estlander rotation flap (Davies and Starr 1945). Shute et al. (1943) review some of the technical methods used.

The unsatisfactory results of treatment have, however, led to no real questioning of the correctness of the standard view of the ætiology—i.e., that pilonidal sinus *is primarily a developmental condition* on which infection has become superimposed. But there has been some speculation about the origin and nature of the developmental abnormality (Peterson and Ames 1944). It is usually regarded as a sequestration dermoid; hence its alternative name of infected postanal dermoid. This view implies that surgical excision of the congenital track should lead to cure; *but often this does not happen.* We have therefore reconsidered the developmental theory and sought some other explanation.

THE DEVELOPMENTAL THEORY

The main evidence for the developmental theory is *(1) that the postanal site is a recognised site for developmental abnormalities*, and (2) that in a fair proportion of cases a dermoid origin is suggested by the presence of epithelial lining, hairs, hair follicles, and sebaceous glands.

(1) *Postanal Site.*—Raven (1935) collected from the pathological museums of London 16 sacrococcygeal cysts and tumours, which most pathologists would consider to be developmental in origin, though they might disagree about the exact derivation. But there is a world of difference between this undoubted developmental condition and a typical pilonidal sinus. The former is situated between the rectum and coccyx, is often first noted in early life, and is rarely the site of secondary infection; whereas the pilonidal sinus is a subcutaneous lesion of the intergluteal cleft, first appears in young adult life, and almost invariably presents as an infected lesion.

Out of 23 cases at the Middlesex Hospital only 2 were of undoubted developmental origin: one in a woman, aged 45 was a typical dermoid cyst extending high up between the rectum and sacrum, lined with skin, hairs, hair follicles and sebaceous glands, and full of inspissated sebaceous material; the other in a woman, aged 24, was a multilocular cyst in the same position, which had been known to have been present since birth and contained, among other tissues, skin with accessory skin structures and cysts lined with columnar epithelium.

Another reason against assessing too highly the argument that the postanal region is a recognised site for developmental abnormalities is that an uninfected sequestration dermoid in the situation of pilonidal sinus is practically never encountered; whereas, if it were the invariable precursor of an infected phase represented by pilonidal sinus, it should be more common. A post-anal dimple is common, but an infective lesion may be directly superimposed on this without the necessity of postulating an intermediate sequestration dermoid.

(2) *Histology.*—The histological appearances of pilonidal sinus have been fully studied and reported. What is usually regarded as the typical picture is a track whose superficial part is lined with *squamous epithelium*, sometimes dilated to form a small cyst, and whose deeper part is lined with *granulation tissue only*. The usual explanation is that the deeper part of the track has lost its original epithelium as a result of the infection (Kooistra 1942); an alternative explanation is that it is a secondary purely infective track developing from the original developmental track. Sometimes no epithelium is found, the track being lined with granulation tissue only, the assumption on the developmental theory being that the epithelium in this case has been completely destroyed. Of the remaining 21 cases of the

Middlesex Hospital series, in 8 only was an epithelial lining demonstrated on routine microscopical section: in the remaining 13 the track was lined with granulation tissue only.

Hairs are more often demonstrated, sometimes macroscopically but more often microscopically. Kooistra (1942) found hairs in just over half of his 89 cases, and in our series of 21 we found hairs in 10.

The exact incidence of *hair follicles* is more difficult to determine, as it is sometimes difficult to decide whether an odd structure surrounded by granulation tissue represents a degenerated follicle or not; but the frequency is certainly much less than that of hairs. Kooistra (1942) found them in only 9% of his cases. In our series, counting as positive every case in which there was the suspicion of a degenerated follicle, we found follicles in 6 out of the 21 cases. In several of these the suspicious follicle was solitary.

Sebaceous glands are much less common. We found none. Kooistra gives an illustration of one example.

The question for decision is whether the presence of the epithelium and structures derived from epithelium in certain cases is conclusive proof of a developmental origin, or whether there is any alternative explanation of their presence.

Sebaceous glands deep in the track are almost conclusive evidence of a sequestration dermoid. But, as we have already stated, this finding is extremely rare and was not present in our series. Sebaceous glands near the opening of the track on the skin might be derived from the surface skin or a postanal dimple.

An *epithelial lining* is not conclusive evidence of a developmental origin. A downgrowth of epithelium along a track lined with granulation tissue to form a deeper epithelial-lined cyst is a well-recognised pathological process and is one of the standard theories invoked to explain, for example, cholesteatoma of the middle ear, and dental cyst. There is also the possibility of the epithelium being implanted by puncture—i.e., implantation dermoid.

Hairs in the track are not necessarily derived from the lining; they might be surface hairs which have penetrated deeply either primarily or secondarily into an already established infective sinus.

Definite *hair follicles* in any number are strong evidence for a sequestration dermoid, but an occasional hair follicle might be implanted (Muir 1941).

Therefore it is only in a very small proportion of cases of pilonidal sinus that evidence from the presence of epithelium or structures derived from epithelium is conclusive or even very strong evidence of a developmental origin; in most cases there are other possible explanations. In other words, though the evidence for the occasional origin of pilonidal sinus in a sequestration dermoid cannot be denied, in most cases there is no incontrovertible evidence of such origin.

RECURRENCES

The developmental theory assumes that, if there is a recurrence, the original track has not been excised completely. But there is a growing feeling that many recurrences cannot be explained on this basis. Barnett (1944) attributes many recurrences to the situation of the lesion in the intergluteal fold, where debris of clothing, lint, hair, and epithelial scales tends to accumulate. Other surgeons attribute recurrence to failure to control infection or to obliterate dead spaces. Davies and Starr (1945) comment on the frequency with which the local application of acridine compounds to the wound after the primary operation leads to recurrence.

But the histology of the excised recurrent sinus does not differ from that of primary pilonidal sinus. Kooistra (1942) found hairs in the tracks in 9 out of 12 recurrent cases. In one case we excised, apparently completely, a primary track which histologically proved to be lined with granulation tissue, with remains of dead hairs in the walls. A recurrent sinus, longer than the primary, developed and was excised. This too was lined with granulation tissue, with dead hairs along the whole length. We were prepared to admit the possibility that in spite of appearances we had left behind a small portion of the primary track. We found it almost impossible to believe that we had left behind, in the same position as the primary track, another even longer track. In another case section of the excised primary track showed a lining of granulation tissue containing hairs; and section of an excised secondary track developing some years later showed an epithelium-lined track containing hairs. It is difficult to avoid the conclusion that some recurrences at any rate are due to some other factor or factors than the leaving behind of a portion of the primary track at operation. And, if these factors can lead to the development of a recurrent track histologically identical with the primary track, may they not also have been the cause of the primary track?

OTHER POSSIBLE CAUSAL FACTORS

In searching for other possible causal factors, a convenient point to start from is the most characteristic twofold feature of pilonidal sinus—the presence of infection and hairs. Either the infection is primary and the hairs are secondary, or the hairs may be the primary cause of the infection.

Primary Infection.—A primary infective origin is supported by the increased incidence in the Services. The intergluteal fold is a region in which infective debris tends to accumulate, and possibly the special incidence in young adults is related to changes in the sweat and sebaceous secretions at this age. The final factor of infection might be gross trauma, such as a fall (Goodsall and Miles 1900), but is more probably the minor trauma of the rubbing together of the buttocks during exercise. An infective sinus once established, hairs and epithelial debris would tend to enter from the depths of the intergluteal fold. This would also explain recurrences.

Hairs.—That hairs might be the direct cause does not seem to have been seriously considered. The condition has been noted particularly in hairy people (Gabriel 1945, Barnett 1944), and we have noted it in some people who were more hairy than normal. But this is not necessarily so and in any case is difficult to prove. Kooistra (1942), who accepts the developmental theory, mentions that Warren (1854) had suggested hairs, inverted on themselves in the follicle, as the cause. But, looking up the reference, we did not confirm this but found instead the statement: "It would seem probable that originally the hair was contained in a cyst."

The fact that epilation doses of X rays (Smith 1937, Turell 1940, Sher 1944) may be of value both preoperatively and in the treatment of recurrence is strong evidence for the causal rôle of hair in the recurrent sinus. And hair might also play a causal rôle in the production of the primary sinus by puncturing the skin and either introducing infection alone or carrying in a small piece of surface skin, thus causing an implantation dermoid. Hairs as a cause of pilonidal sinus cannot therefore be dismissed.

SIMILAR LESION IN A BARBER'S HAND

We have recently seen a pilonidal sinus in a barber's hand.

A barber, aged 31, came to hospital with a discharging sinus on the dorsum of the interdigital cleft between the ring and little fingers of the right hand. He attributed it to a hair penetrating the skin at this point while he was cutting a customer's hair. He pulled it out, but a discharging sinus developed and persisted, and at his work other hairs tended to enter the sinus.

On examination a small nodule the size of a pea could be felt just behind the orifice of the sinus, and a probe could be passed into this nodule from the orifice of the sinus. The sinus and nodule were excised and the skin sutured. The wound healed uneventfully.

The histological picture was exactly like that of a postanal pilonidal sinus. The sinus led into a cavity lined with squamous epithelium and containing a hair follicle, and the deeper part was a track lined with granulation tissue and containing hair and debris in its walls.

The history of this case and the difficulty of any developmental explanation in this situation are strong evidence that this case is an example of pilonidal sinus due to the puncture of the skin by a hair.

Our patient said that a friend of his, also a barber, had a similar condition, which arose in the same way. So we sought for further examples. Assistants in two well-known London hairdressing firms said that it was not at all uncommon for minor infective lesions to be produced owing to puncture of the skin during haircutting, particularly in the hands. Usually they cleared without serious trouble after the removal of the hair. Occasionally, however, a more chronic lesion resulted, and we were told of one such case in which a legal action followed; but we could not trace the legal records. From our inquiries it is obvious that among barbers hair is well recognised as a traumatic and infective agent.

CONCLUSIONS

Pathology.—Critical analysis of the developmental theory of pilonidal sinus leads to the conclusion that though a small proportion of cases arise in a previously existing postanal dermoid, in the great majority of cases there is no definite evidence of such origin. Moreover, many of the features of recurrence are difficult to fit in with the developmental theory. Alternative possibilities are that pilonidal sinus is primarily an infective lesion, with secondary entrance of hair and debris, or the result of penetration of the skin by a hair, which may also introduce both infection and epithelium. We suggest that these alternative possibilities are more in accord with the facts.

Treatment.—If the developmental theory of pilonidal sinus is relegated to a subordinate place, the rational treatment of the condition demands corresponding adjustment. No longer need such emphasis be laid on the extent of the primary excision, which on the developmental theory led in many cases to a probably unnecessary removal of tissue, with consequent prejudice to the subsequent healing. Though measures short of surgical excision of the track may be successful in cases in which the lining is merely granulation tissue, excision will probably continue to be the standard treatment, because *it is impossible to tell clinically whether an epithelial* track is present or not and to remove the hairs which are acting as foreign bodies. The main emphasis in treatment becomes transferred to securing healing of a chronic infective condition at the bottom of a fold. If the causal rôle of hairs, both in the primary lesion and in recurrences, is as important as we believe, a preoperative epilation dose of X rays becomes an essential part of treatment. The results of Smith (1937), Turell (1940), and Sher (1944) offer practical encouragement to this point of view.

SUMMARY

The increased interest in pilonidal sinus as the result of the war has emphasised the dissatisfaction of surgeons with the uncertainties of its treatment, which has been reflected in a wide variety of surgical procedures.

We have therefore submitted the accepted developmental theory of pilonidal sinus to critical analysis. As a result, we conclude that, though a small proportion of cases are developmental in origin, the great majority may be acquired infective lesions, hair playing an important rôle in the production both of the primary lesion and of recurrences.

A similar lesion in a barber's hand is described.

The emphasis in treatment should be shifted from attempting a wider eradication by excision to the management of a chronic infective lesion in a fold.

A preoperative epilation dose of X rays to the area should be a routine.

LATE SQUADRON-LEADER R.A.F.V.R.

THE published results of nicotinamide methochloride estimations in pellagra (Ellinger et al. 1945) seemed to us to justify a similar investigation in active and convalescent cases of sprue, and offered a means of assay of a vitamin-B factor related to sprue.

We intended to include in the investigation amœbiasis, bacillary dysentery, and the chronic non-specific diarrhœas to try to determine the effects, if any, of intestinal infection on nicotinamide excretion; but unfortunately we could not collect any cases of bacillary dysentery or of chronic non-specific diarrhœa.
